What do we know about severity?

Initial aphasia severity associated with poorer outcomes; patients with milder aphasia show greater recovery (Laska et al., 2001; Pederson et al., 2004; Plowman et al., 2011)

Initial severity has a negative effect on outcome of stroke rehabilitation (van Bragt, 2014)

Using technology to improve treatment delivery

- ▶ Recent studies have examined the efficacy of rehabilitation techniques, such as videoconferencing, for individuals with hearing, stuttering and motor speech issues (Georgeadis et al., 2004; Hill et al., 2006).
- ▶ Other studies have provided aphasia therapy over the internet to individual patients (Goral et al., 2010; 2011).
- ▶ Virtual Therapy programs: Sentactics (Thompson, Choy, Cole & Holland, 2010); ORLA-VT; (Cole, Cherney et al).
- ▶ Computerized rehabilitation programs:
 - ▶ Multicue (Doesborgh, van de Sandt-Koenderman, 2004).
 - ▶ MossTalk (Fink et al, 2002).
 - ▶ Other computerized methods (Palmer et al., 2012; Rambserger & Marie, 2007).
 - ▶ Software platforms such as Constant Therapy (Des Roches et al., 2015).

The delivery of tablet-based rehabilitation for individuals with post-stroke aphasia is relatively new, therefore, this study examined the effectiveness of an iPad-based therapy to demonstrate improvement in specific therapy tasks and how the tasks affect overall language and cognitive skills. Fifty-one individuals with aphasia due to a stroke or traumatic brain injury (*TBI*) were recruited to use an iPad-based software platform, Constant Therapy, for a 10 week therapy program. Participants were split into an experimental ($N = 42$) and control ($N = 9$) group. Both experimental and control participants received a 1 h clinic session with a clinician once a week, the experimental participants additionally practiced the therapy at home. Participants did not differ in the duration of the therapy and both groups of participants showed improvement over time in the tasks used for

SUPPLEMENTAL DATA

Table 1.DOCX

- 51 patients with stroke or TBI
- 42 experimental patients and 9 control patients
- Both groups matched for WAB AQ, CLQT composite severity and age
- Both groups practiced Constant Therapy on their ipads.

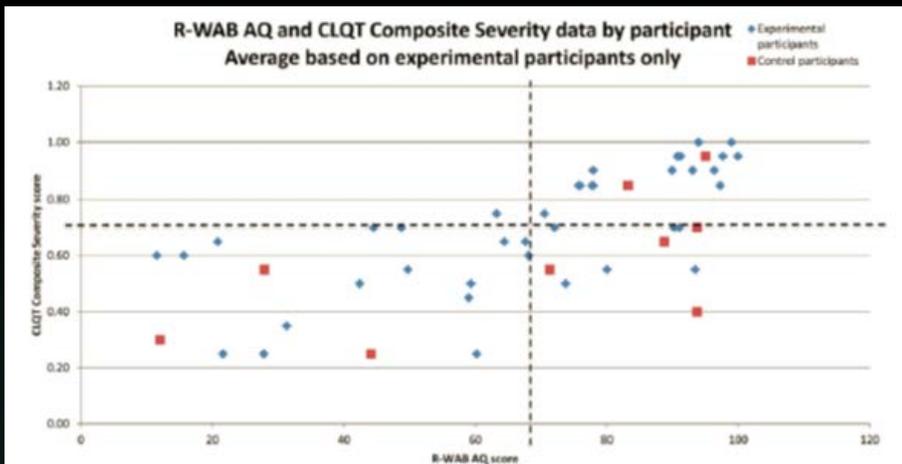

FIGURE 2 | Scatter plot of low vs. high deficits in R-WAB AQ (x-axis) and CLQT Composite Severity (y-axis) by patient. The dotted lines denote the average R-WAB AQ and average CLQT Composite Severity score for experimental participants to provide more information for Table 3B.

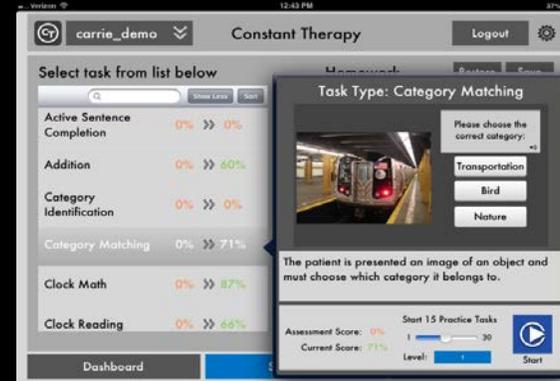

Assess baseline performance

- Language and cognitive skills

Assign individualized set of tasks

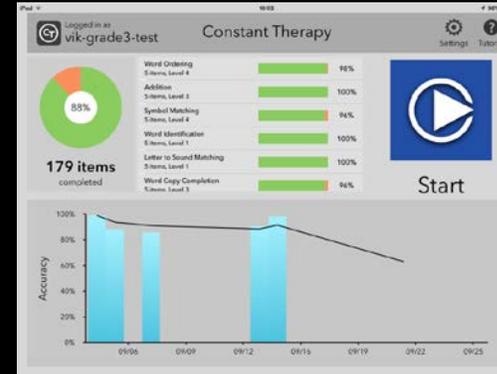

Task assigned if accuracy less than 80% on first session

Assess baseline performance

- Language and cognitive skills

Assign individualized set of tasks

Patient performs tasks

Experimental patients in clinic and home
Control patients in clinic only

Assess baseline performance

- Language and cognitive skills

Assign individualized set of tasks

Patient performs tasks

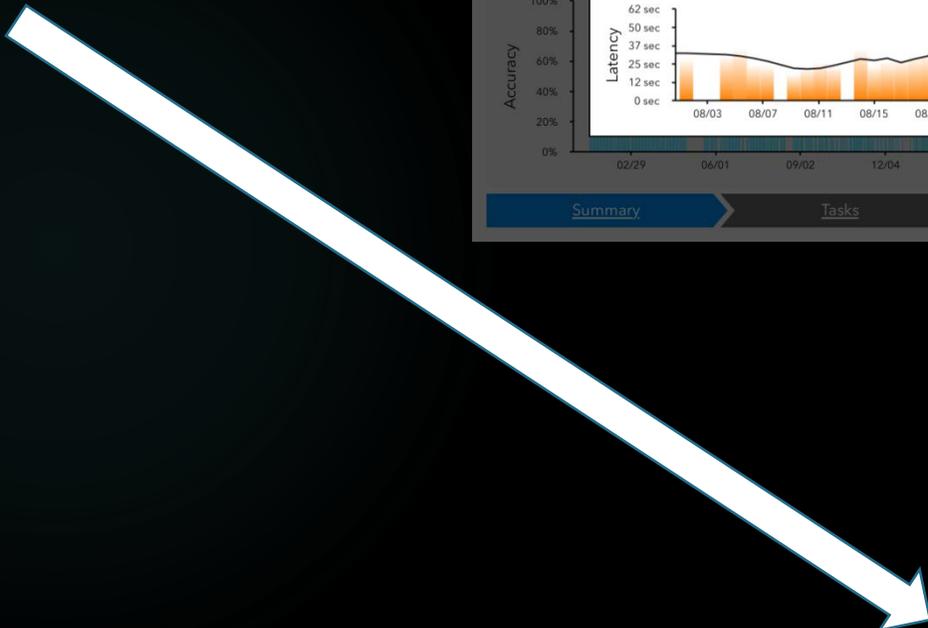

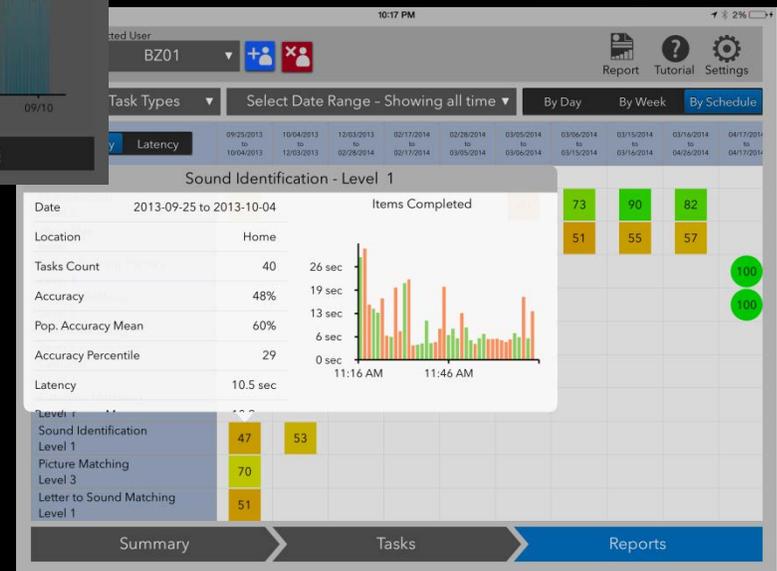

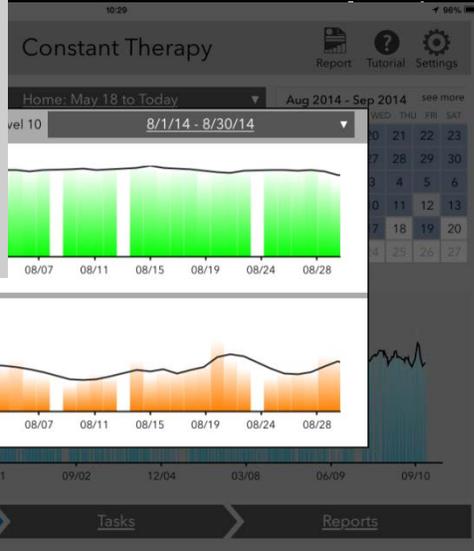

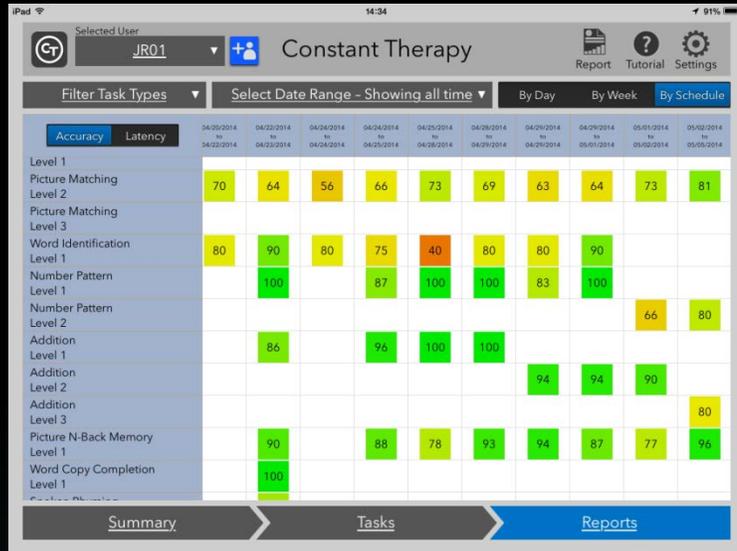

- Experimental patients in clinic and home
- Control patients in clinic only

Clinician monitors progress and alters plan

Weekly clinic sessions

- ▶ Keep the task or modify the task
- ▶ If the participant achieved 95% or higher accuracy two times in succession,
 - ▶ The clinician would either progress the next level of difficulty or different task.
- ▶ If a participant was not improving on a task over time,
 - ▶ Either a lower level of that task was assigned in addition to or in replacement of the original task,
 - ▶ A different task examining the same skill,
 - ▶ No change.

Individual patient level

CLQT- Visuospatial skills	6.89 (t = -3.45, p < .001)	2.96% (ns)

Experimental patients show more significant changes on standardized tests than control patients.

Patients with lower initial scores showed more improvements on the standardized tests than patients with higher initial scores.

What can we understand about severity?

The **more severely** language-impaired participants tended to benefit from the simpler tasks (e.g., category matching) that were assigned.

The **less severely** language-impaired participants benefit from more difficult tasks and those that combined language and cognitive skills.

Patients with **lower initial scores** showed more improvements than patients with **higher initial scores**.

Possible to better tailor treatment based on starting level severity of impairment across a group of patients.

Not only can examine quantitative measures that we are used to looking such as accuracy and latency.

We can even begin to look at more qualitative metrics such as scaffolds.

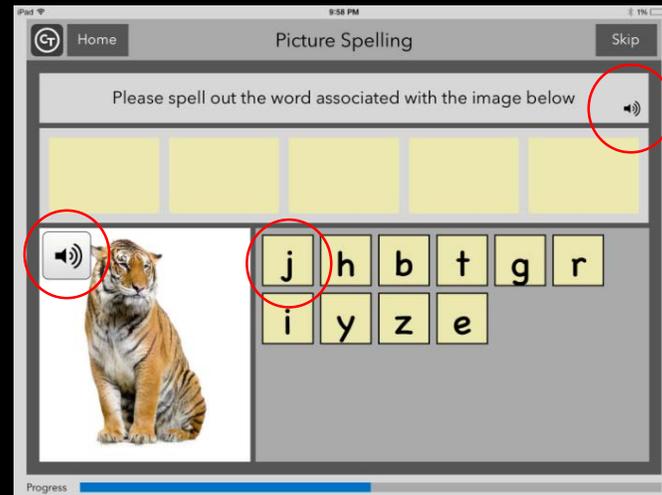

Quantify the way patients interact with therapy.

Follow up- Study #2

- ▶ Examined individual differences in the way patients used cues to solve the tasks.
- ▶ 51 individuals with aphasia,
- ▶ 10 week therapy program using the Constant Therapy software platform,
- ▶ Participants could self-administer hints (available in 28 of the 37 tasks).

Hint use and accuracy

- ▶ Examined individual differences in the way patients used cues to solve the tasks.
- ▶ 51 individuals with aphasia,
- ▶ 10 week therapy program using the Constant Therapy software platform,
- ▶ Participants could self-administer hints (available in 28 of the 37 tasks).

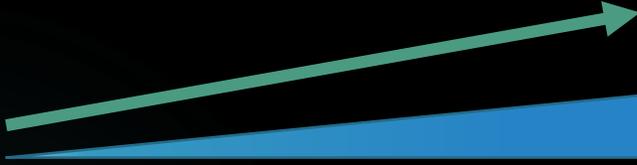

What is the relationship between accuracy and hint use?

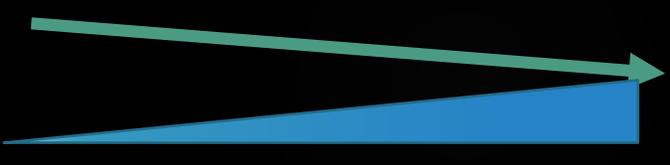

- ▶ First, a simple regression of the count of all hints self-administered within a session and average accuracy within the session for all participants
 - ▶ Hint use had a significant **negative predictive** relationship with accuracy.
- ▶ K-means cluster analysis for sample participants.

What is the relationship between accuracy and hint use?

- ▶ First, a simple regression of the count of all hints self-administered within a session and average accuracy within the session for all participants
 - ▶ Hint use had a significant **negative predictive** relationship with accuracy.
- ▶ K-means cluster analysis for sample participants.

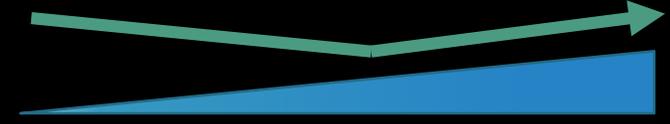

Participant 12	Cluster 1	Cluster 2	Cluster 3	Cluster 4	Cluster 5
Average Accuracy	92%	92%	97%	100%	100%
Average Hint Use	<1	9	19	28	44
Number of Cases	275	11	5	7	2

Participant 18	Cluster 1	Cluster 2	Cluster 3	Cluster 4	Cluster 5
Average Accuracy	87%	80%	76%	71%	67%
Average Hint Use	<1	16	27	42	57
Number of Cases	319	125	64	17	3

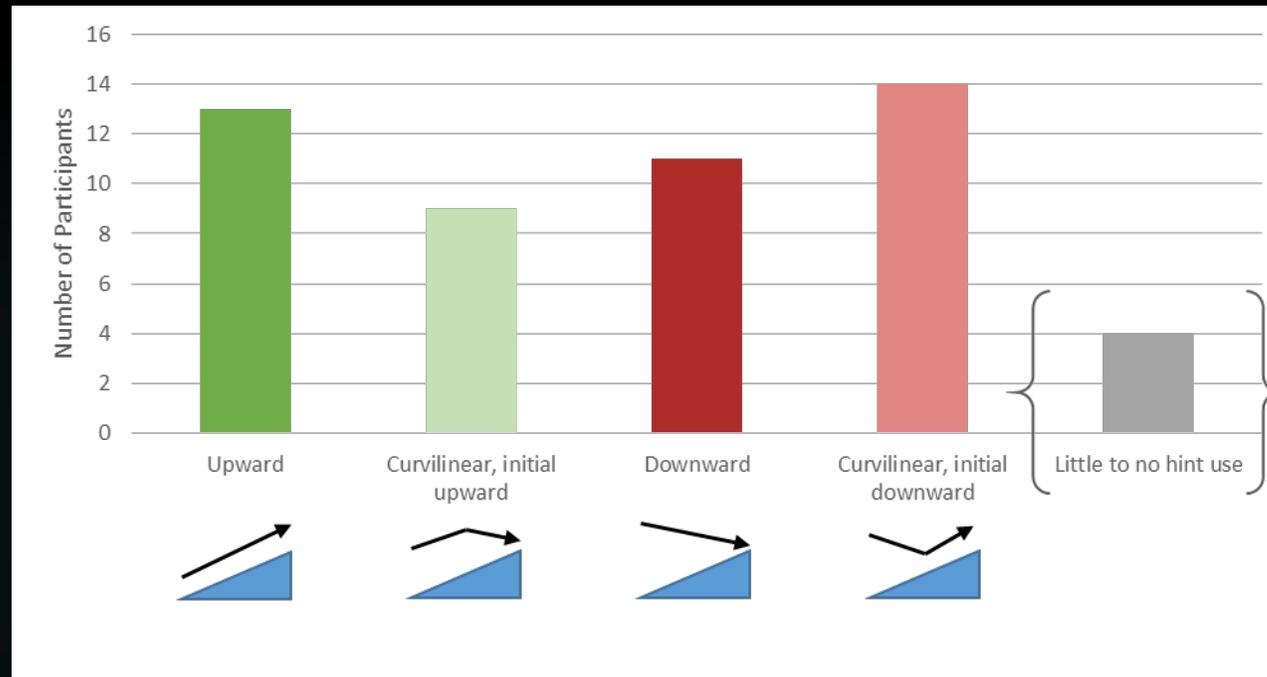

Participant 34	Cluster 1	Cluster 2	Cluster 3	Cluster 4	Cluster 5
Average Accuracy	80%	79%	92%	89%	88%
Average Hint Use	1	11	26	38	58
Number of Cases	82	26	4	4	3

Participant 2	Cluster 1	Cluster 2	Cluster 3	Cluster 4	Cluster 5
Average Accuracy	74%	68%	65%	74%	77%
Average Hint Use	<1	8	16	28	39
Number of Cases	255	144	30	10	5

What is the relationship between accuracy and hint use?

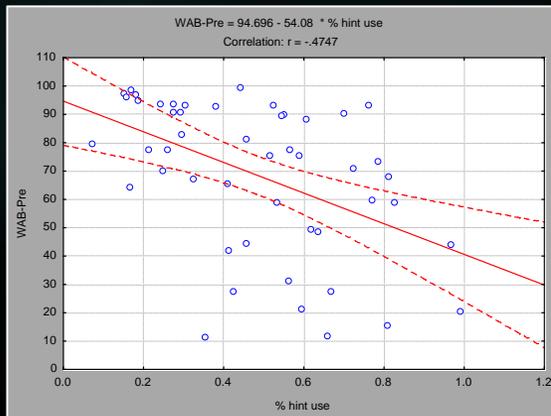

Patients form five subgroups in terms of whether increased hint use is associated with increased accuracy.

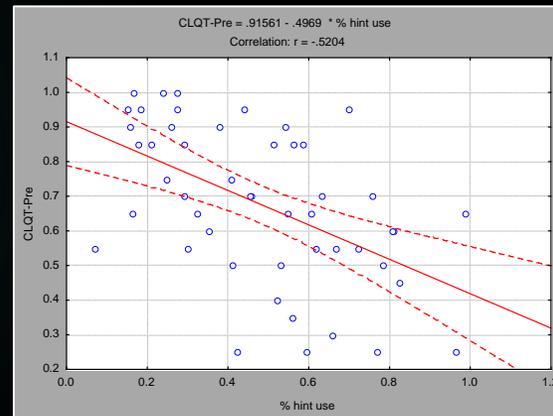

Are participants' severity profiles related to frequency of self-administered hint use?

- ▶ Pearson correlation of frequency of hint use with all standardized test scores and demographic information,
- ▶ All severity measures negatively correlated with frequency of hint use,
- ▶ The **more severe** the participant, the **more frequently** they used hints.

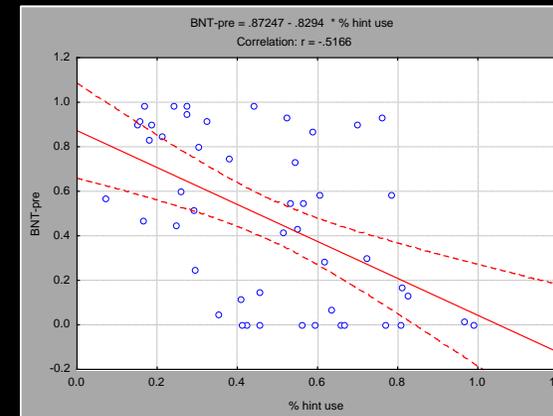

WAB & Hint use

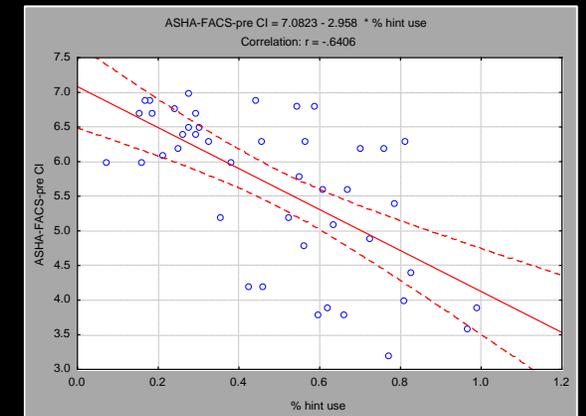

CLQT & Hint use

BNT & Hint use

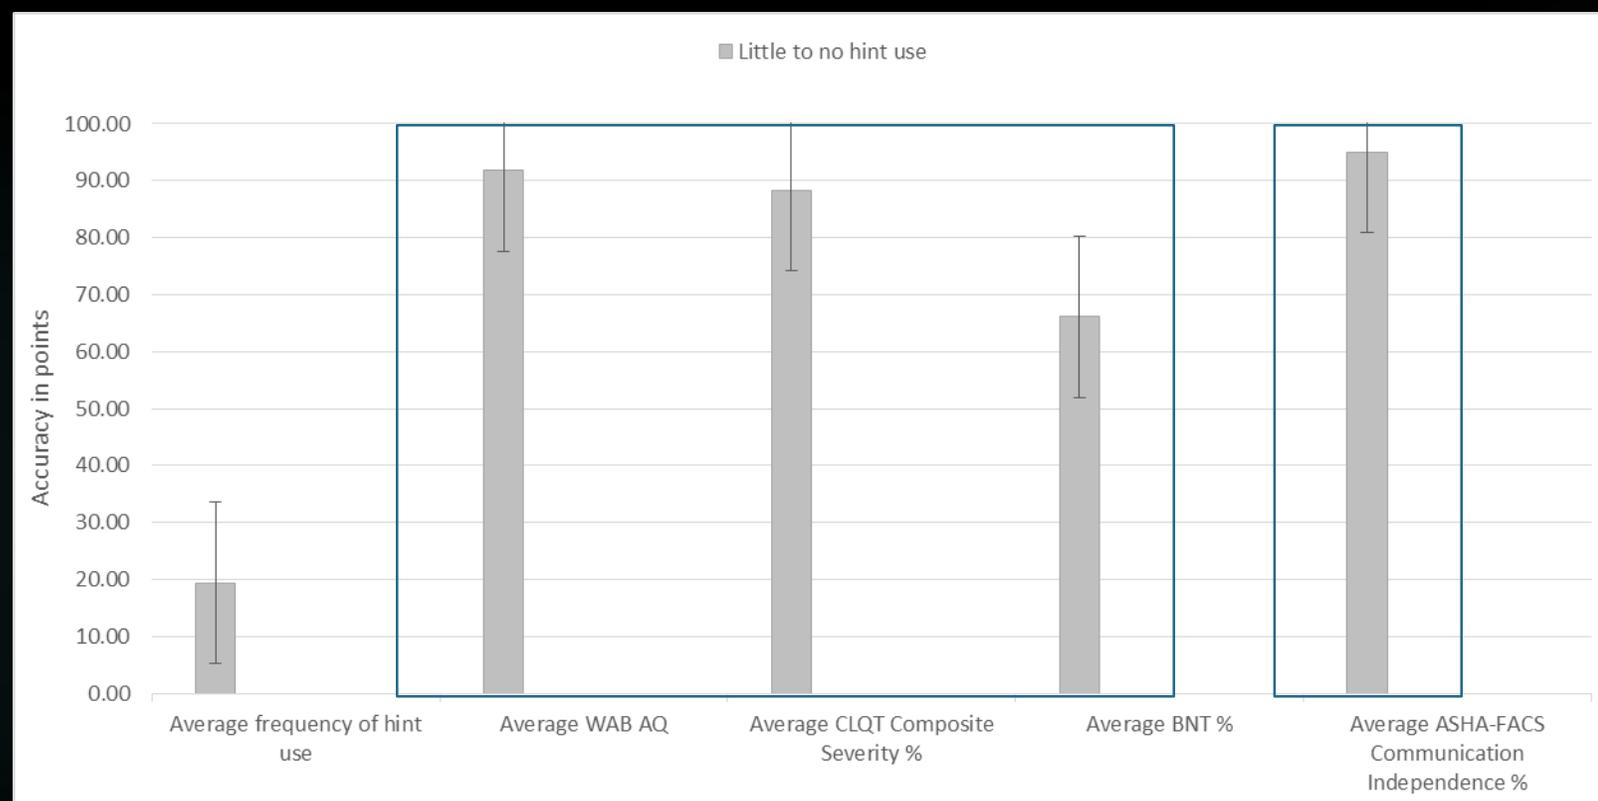

ASHA FACS CI & Hint use

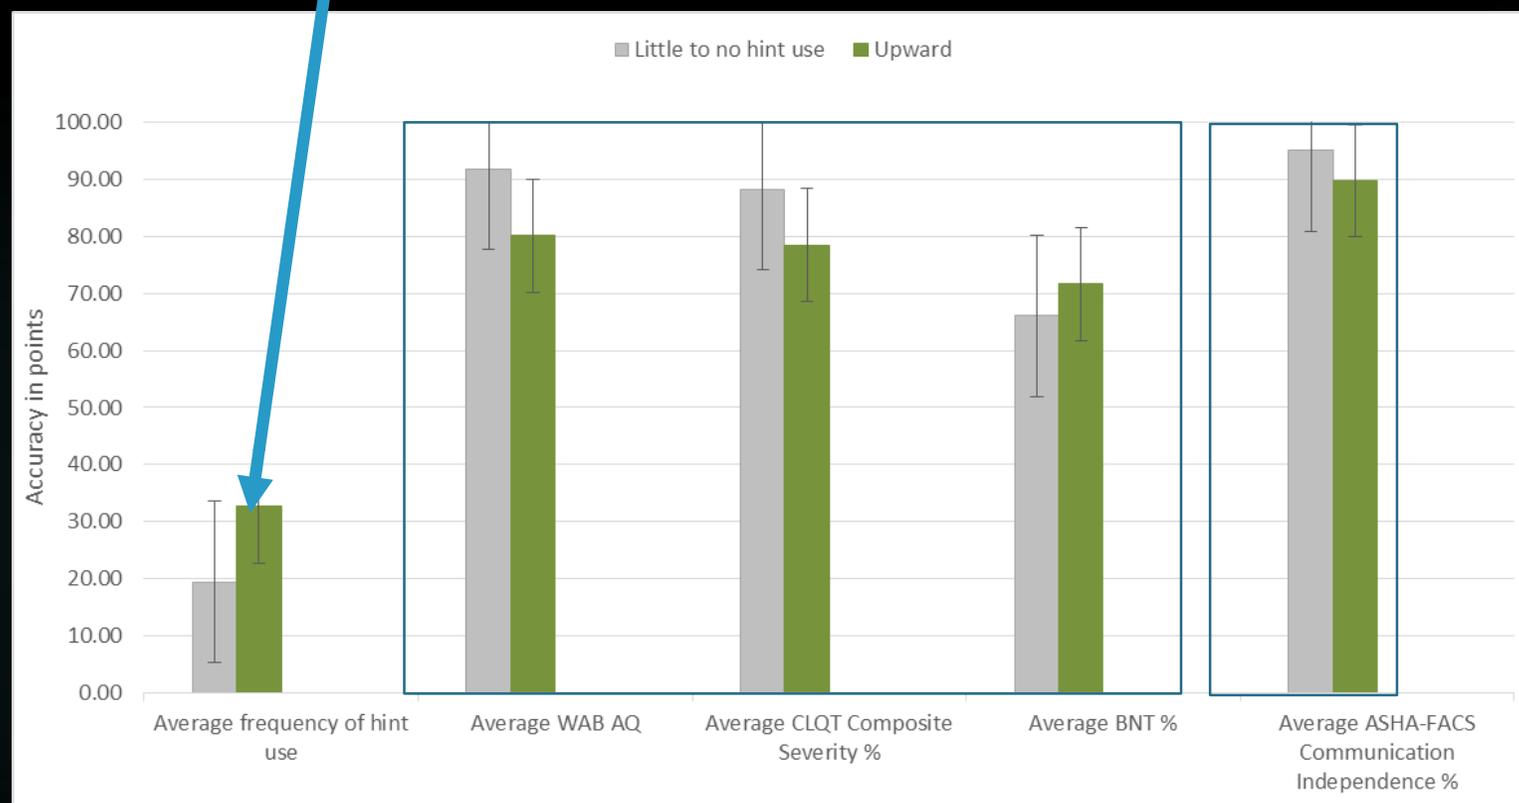

- ▶ Combining severity and frequency of hint use
- ▶ Overall accuracy on task ranged between 75%-85%

These participants used hints infrequently and had the highest scores on most of the standardized measures.

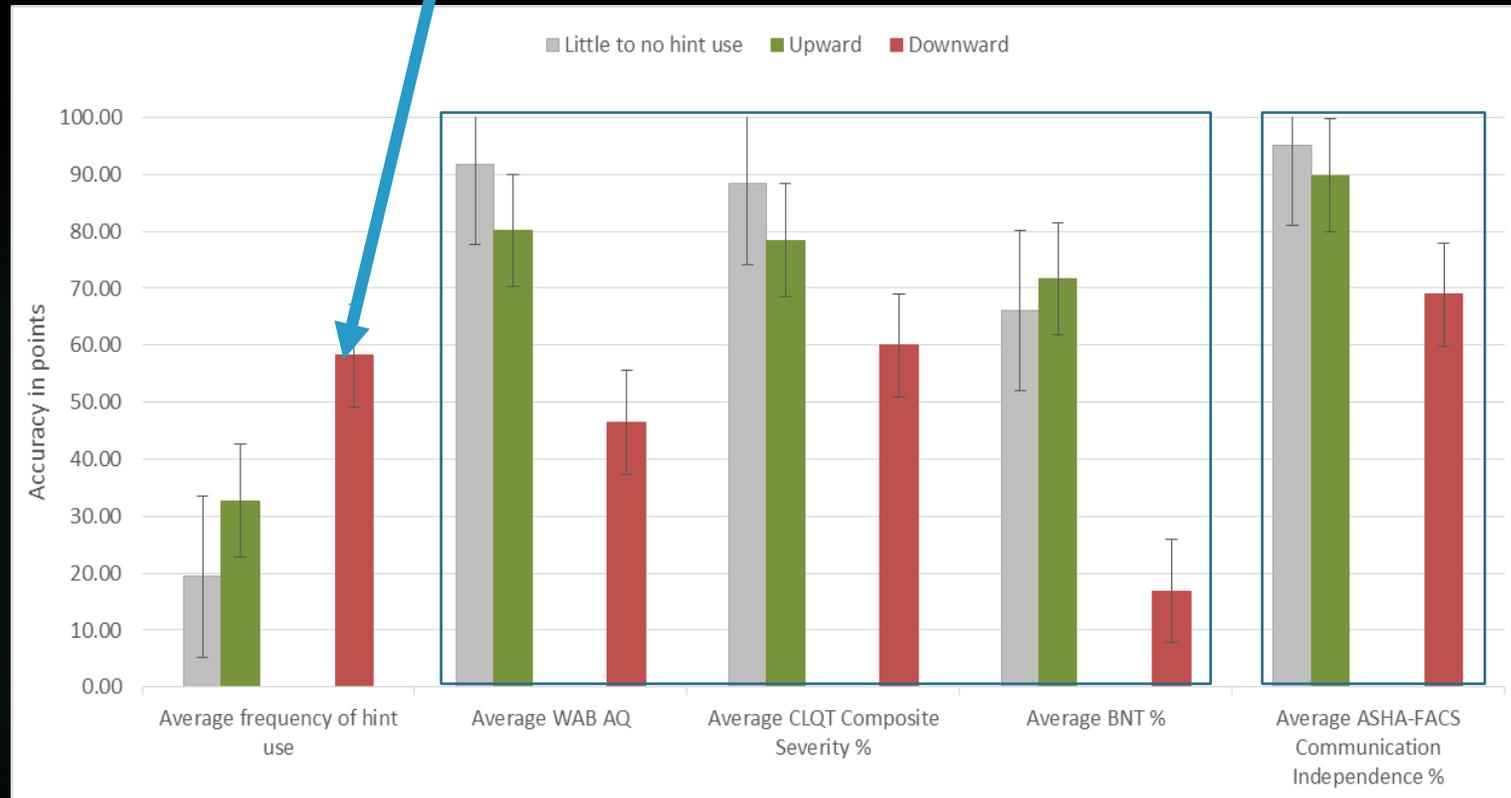

► Combining severity and frequency of hint use

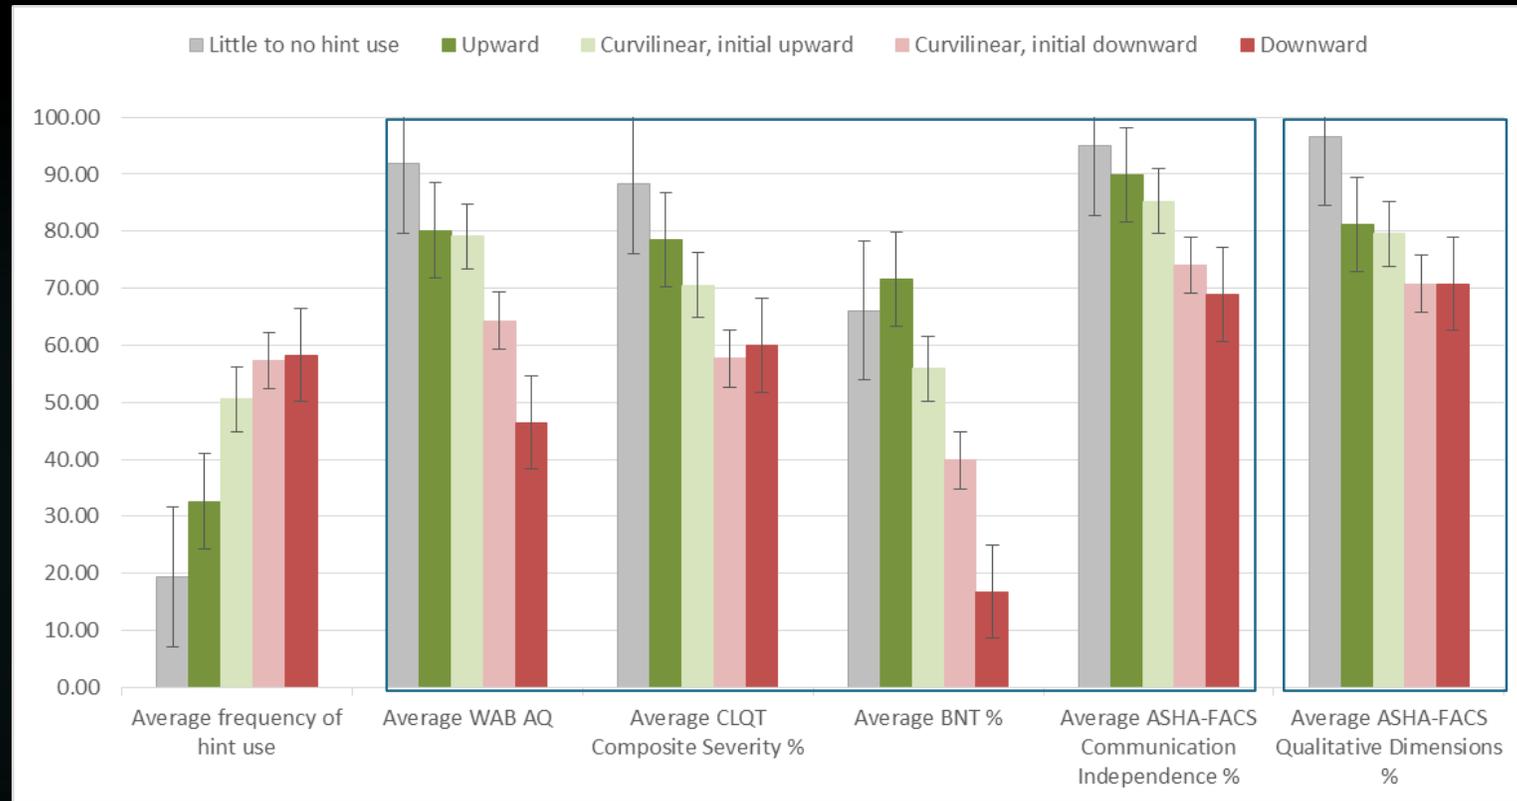

Low but beneficial hint use

► Combining severity and frequency of hint use

High but non-beneficial hint use

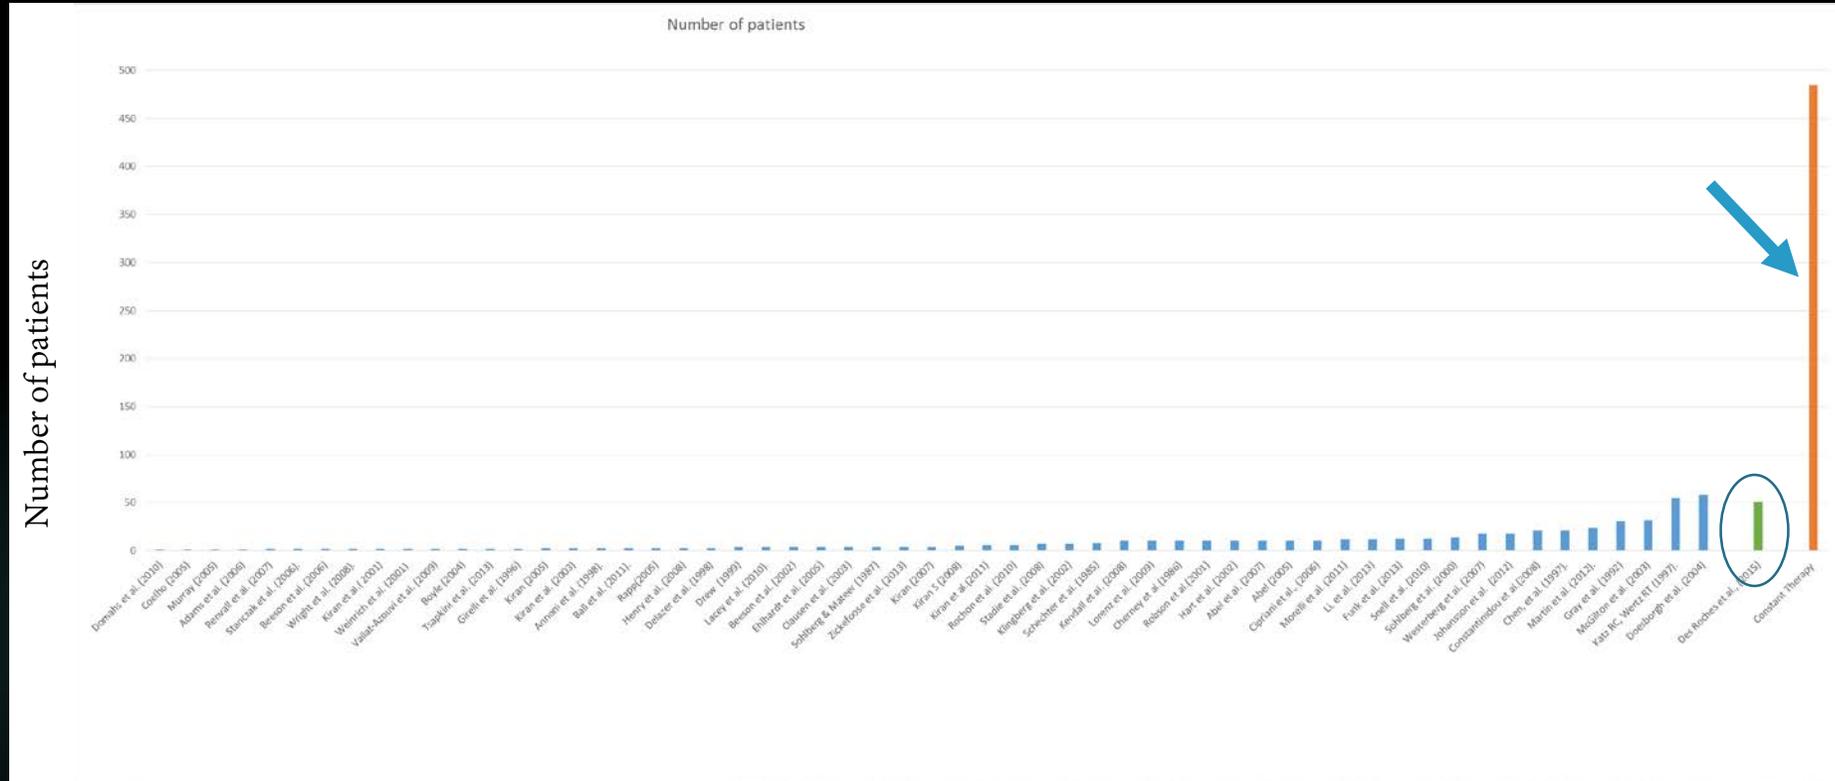

What does this tell us about severity?

The more severe patients (based on the standardized tests) also used hints more frequently, but this higher hint use was not beneficial.

The less severe patients (based on the standardized tests) used hints less frequently, but this hint use was beneficial for them.

Has implications for the way self-administered hints or clinician-generated cues may help or hinder patients during rehabilitation.

How can big data inform clinical decision making?

Case –studies,
SSED

Approach for CT data

- ▶ Patients download the app and sign up for an account.
- ▶ Based on an initial baseline assessment, a given task is assigned as long as its performance is between 40% and 90% accuracy and average latency.
- ▶ For the analysis, for given task type and level :
 - ▶ Compared post-tx performance (Average of the last 10 items for each patient) – pre-treatment performance (average of the first 10 items for each patient).
 - ▶ Drop the first three items of a given task.
- ▶ Paired t-test (two tailed) per task; Only consider $p < .05$ as statistically significant changes.
- ▶ Same analysis for accuracy and latency.

What does this tell us about severity?

What does this tell us about severity?

Worse starting performance does not indicate poorer outcomes.

Moderate-severely impaired patients can make strong gains in treatment.

Implications for providing therapy services for the more severe-impaired patients.

Future Direction

- ▶ We are really only at the beginning of accessing big data.
- ▶ Lot more work needs to be done.
- ▶ But we have the tools to examine and understand the factors that contribute to rehabilitation outcomes.
- ▶ Future work examine different types of control conditions.
- ▶ Relationship between symptomatology and treatment gains.
