Abstract: The aim of the present study is to investigate the effect and potential mechanism of action of 6-gingerol on alterations of vascular reactivity in the isolated aorta from diabetic rats. Male Wistar rats were divided into two experimental groups, control and diabetics. Diabetes was induced by a single intraperitoneal injection of streptozotocin (50 mg kg⁻¹), and the rats were left for 10 weeks to develop vascular complications. The effect of in vitro incubation with 6-gingerol (0.3–3 μM) on the vasoconstrictor response of the isolated diabetic aortae to phenylephrine and the vasodilator response to acetylcholine was examined. Effect of 6-gingerol was also examined on aortae incubated with methylglyoxal as an advanced glycation end product (AGE). To investigate the mechanism of action of 6-gingerol, the nitric oxide synthase inhibitor N^ω-nitro-L-arginine methyl ester hydrochloride (100 μM), guanylate cyclase inhibitor methylene blue (5 μM), calcium-activated potassium channel blocker tetraethylammonium chloride (10 mM), and cyclooxygenase inhibitor indomethacin (5 μM) were added 30 minutes before assessing the direct vasorelaxant effect of 6-gingerol. Moreover, in vitro effects of 6-gingerol on NO release and the effect of 6-gingerol on AGE production were examined. Results showed that incubation of aortae with 6-gingerol (0.3–10 μM) alleviated the exaggerated vasoconstriction of diabetic aortae to phenylephrine in a concentration-dependent manner with no significant effect on the impaired relaxatory response to acetylcholine. Similar results were seen in the aortae exposed to methylglyoxal. In addition, 6-gingerol induced a direct vasodilation effect that was significantly inhibited by N^ω-nitro-L-arginine methyl ester hydrochloride and methylene blue. Furthermore, 6-gingerol stimulated aortic NO generation but had no effect on AGE formation. In conclusion, 6-gingerol ameliorates enhanced vascular contraction in diabetic aortae, which may be partially attributed to its ability to increase the production of NO and stimulation of cyclic guanosine monophosphate.

Keywords: diabetes, 6-gingerol, vasorelaxant, nitric oxide, advanced glycation end products, vascular complications

Introduction

Diabetes mellitus (DM) is a common disease that affects almost 387 million people worldwide with a prevalence of 8.3% and an expected 205 million increase by 2035, according to the International Diabetes Federation.¹ Despite significant improvements in controlling diabetes, vascular complications remain a major cause of morbidity and mortality in patients with DM.² Macrovascular complications of DM include coronary artery disease,³ heart failure,⁴ and stroke.⁵ In addition, microvascular diseases of DM, including nephropathy⁶ and retinopathy,⁷ continue to cause morbidity and mortality. These vascular complications may be partially attributed to impairment of vasomotor function of smooth muscles.^{8,9}

Ginger rhizome (*Zingiber officinale*), commonly known as ginger, is utilized worldwide as a spice and a flavoring agent, with a long history of medicinal use for diseases, including arthritis, pain, sore throat, constipation, indigestion, vomiting, dementia, fever, infectious diseases, and helminthiasis.¹⁰ Moreover, it is used in South Asia as a traditional medicine to treat cardiopathy and hypertension due to its vasodilator effect.¹¹ Phytochemical reports showed that the main constituents of ginger are the gingerols, shogaols, zingerone, and paradol.¹² 6-Gingerol, one of the major elements of ginger, has been found to exhibit anti-inflammatory,¹³ antihyperglycemic,¹⁴ antiangiogenic,¹⁵ and anticancer¹⁶ effects. In addition, antiplatelet aggregatory and vasorelaxatory effects of the constituents of ginger were reported by Liao et al.¹⁷ Hence, the current study is designed to investigate the effect and potential mechanism of action of 6-gingerol on alterations of vascular reactivity in the isolated aorta from diabetic rats.

Materials and methods

Drugs and chemicals

6-Gingerol, N ω -nitro-L-arginine methyl ester hydrochloride (L-NAME), methylene blue (MB), tetraethylammonium chloride (TEA), indomethacin (INDO), aminoguanidine (AG), ribose, bovine serum albumin (BSA), acetylcholine (ACh), and phenylephrine (PE) were purchased from Sigma-Aldrich Co., St Louis, MO, USA, and 4-amino-5-methylamino-2',7'-difluorofluorescein (DAF-FM) diacetate was purchased from Molecular Probes, NY, USA. All chemicals were dissolved in ultrapure deionized water except for 6-gingerol, DAF-FM diacetate, and INDO, which were dissolved in dimethyl sulfoxide (DMSO). The final DMSO concentration did not exceed 0.1% that has no effect on vascular reactivity according to our preliminary studies.

Animals

Male Wistar rats (King Abdulaziz University, Saudi Arabia) weighing 120–140 g, aged 6 weeks, were housed in clear polypropylene cages (three to four rats per cage) and kept under constant environmental conditions with equal light–dark cycle. The rats had free access to commercially available rodent pellet diet and purified water. All the experimental procedures were performed in accordance with Saudi Arabia Research Bioethics and Regulations, which are consistent with the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health. The experimental protocol was approved by the Unit of Biomedical Ethics Research Committee, King Abdulaziz University.

Study protocol

The animals were randomly divided into two experimental groups: control (C) and diabetic (D) groups (six to eight rats in each group). Diabetes was induced by a single intraperitoneal injection of streptozotocin (STZ, 50 mg kg⁻¹). Glucose levels in tail blood were determined using a glucose meter (ACCU-CHEK; Hoffman-La Roche Ltd., Basel, Switzerland) with noble metal electrode strips. Diabetes was confirmed by a stable hyperglycemia (blood glucose levels of 250–350 mg dL⁻¹) after 2 weeks of STZ injection. The rats were left for an additional 8 weeks to develop vascular complications, based on the results of a recent work from our laboratories.¹⁸ The animals were then killed by decapitation with rodent guillotine, and the descending thoracic aorta was carefully excised and placed in cold Krebs–Henseleit buffer with the following composition (mM): NaCl 118.1, KCl 4.69, KH₂PO₄ 1.2, NaHCO₃ 25.0, glucose 11.7, MgSO₄ 0.5, and CaCl₂ 2.5. The aorta was then cleaned of fat and connective tissue and cut into three rings (~3 mm length).

Vascular reactivity

Vascular reactivity of the isolated thoracic aortae was determined using the isolated artery techniques described in previous publications from our laboratories.^{19,20} Isolated aortae from the diabetic group were incubated with different concentrations of 6-gingerol (0.3–10 μ M) for 30 minutes before assessing the vasoconstriction and vasodilation responses, whereas the isolated aortae from the control group were incubated in DMSO. For assessing the aortic contractile responsiveness, increases in tension due to cumulative additions of PE (1 nM to 10 μ M) were recorded and expressed as milligram tension per milligram tissue wet weight. In order to study the vasodilator responsiveness of the aorta, the aortic rings were first precontracted with maximal concentrations of PE (10 μ M). Cumulative concentrations of ACh (1 nM to μ M) were then added to the organ bath and the response was recorded as percentage in relation to PE precontraction.

Exposure of aortae to advanced glycation end products

Aortae isolated from the control animals were incubated with methylglyoxal (MG, 200 μ M) for 60 minutes with or without different concentrations of 6-gingerol (0.3–3 μ M) before studying the vasoconstriction response to PE and vasodilation response to ACh as described in the diabetic aortae experiments.

Direct vasodilation effect of 6-gingerol

A set of experiments were carried out to investigate the direct vasorelaxant effect and mechanism of action of 6-gingerol. Cumulative concentrations of 6-gingerol (0.3–10 μ M) were added to the organ bath containing the isolated aortae precontracted with PE (10 μ M) and the decrease in tension was recorded.

In other sets of experiments, the nitric oxide synthase inhibitor L-NAME (100 μ M), guanylate cyclase inhibitor MB (5 μ M), calcium-activated potassium channel blocker TEA (10 mM), or cyclooxygenase inhibitor INDO (5 μ M) was added 30 minutes before investigating the direct vasorelaxant effect of 6-gingerol as described earlier. The results of 6-gingerol effects were expressed as log *M*.

ACh-induced NO generation

Intracellular NO generation following ACh activation of the isolated aorta was investigated using the fluorescence probe DAF-FM diacetate as described in a previous work from our laboratories.¹⁸ Briefly, the isolated aortae were added to 96-well black plates containing 110 μ L saline and 2.5 μ M DAF-FM with or without ACh or 6-gingerol (both at 1 mM) and incubated for 3 minutes at 37°C. Then, volumes of 90 μ L were transferred to new wells, and the fluorescence intensity was measured at an excitation wavelength of 485 nm and an emission wavelength of 525 nm using a monochromator SpectraMax® M3 plate reader.

Advanced glycation end product formation

The effect of 6-gingerol on advanced glycation end product (AGE) formation was assessed according to a previously reported method.²¹ Briefly, 10 mg mL⁻¹ BSA was incubated with 100 mM ribose in 100 mM phosphate-buffered saline (pH 7.4) containing 0.02% sodium azide at 37°C for 2 weeks in the absence or presence of 6-gingerol (1–1,000 μ M) and AG (1 mM). The formation of fluorescent AGE was measured using a monochromator SpectraMax® M3 plate reader. The fluorescence intensity was measured at an excitation wavelength of 355 nm and an emission wavelength of 460 nm.

Statistical analysis

Values are expressed as mean \pm standard error of the mean. Statistical analysis was performed by the one- or two-way analysis of variance followed by Dunnett's post hoc test using the statistical software Prism 5® (Graphpad Software, Inc., La Jolla, CA, USA).

Results

Effect of 6-gingerol on vascular reactivity of diabetic aortae

Diabetic aortae showed exaggerated vasoconstriction in response to PE (10⁻⁹ to 10⁻⁵ M) compared with control aortae. This enhancement of vasoconstriction was highly significant ($P < 0.001$) at PE concentrations of 3×10^{-7} to 10⁻⁵ M (Figure 1A). Incubation with 6-gingerol (0.3–10 μ M) for 30 minutes alleviated the exaggerated vasoconstriction of diabetic aortae in a concentration-dependent manner. The inhibition of PE (10⁻⁵ M)-induced contraction was highly significant ($P < 0.001$) at 3 μ M 6-gingerol and was significant ($P < 0.05$) at 10 μ M 6-gingerol (Figure 1A).

Diabetic aortae showed impaired vasodilation in response to ACh (10⁻⁹ to 10⁻⁵ M) compared with control aortae, which was highly significant ($P < 0.001$) at an ACh concentration of 10⁻⁵ M. In contrast to the effects on PE-induced contraction, there was no significant effect of 6-gingerol (0.3–10 μ M) on the relaxant effect of ACh (10⁻⁹ to 10⁻⁵ M; Figure 1B).

Effect of 6-gingerol on vascular reactivity of aortae exposed to AGE

Incubation of diabetic aortae with MG produced exaggerated vasoconstriction in response to PE compared with control aortae (Figure 2), with an enhanced *E*_{max} and shift in pEC₅₀. These differences in contraction were highly significant ($P < 0.001$) at 3×10^{-8} and 10⁻⁷ M PE concentrations (Figure 2A). 6-Gingerol (3 μ M) showed a significant ($P < 0.05$) alleviation of the exaggerated vasoconstriction in response to 10⁻⁸ and 10⁻⁵ M PE concentrations (Figure 2A). MG produced significant ($P < 0.01$) impairment in aortic vasodilation induced by ACh (3×10^{-6} and 10⁻⁵ M) in the diabetic aortae compared to that in the control aortae, while there was no significant effect of 0.3–10 μ M 6-gingerol (Figure 2B).

Direct vasorelaxant effect of 6-gingerol

Addition of cumulative concentrations of 6-gingerol (3×10^{-5} to 10⁻³ M) to the organ bath resulted in a concentration-dependent vasodilation in the isolated diabetic aortae precontracted with PE that was statistically significant ($P < 0.001$) at 6-gingerol concentrations of 3×10^{-4} and 10⁻³ M. Preincubation with L-NAME or MB (at 100 and 5 μ M) for 30 minutes before the cumulative addition of 6-gingerol significantly inhibited the vasodilation effect of 6-gingerol (both at $P < 0.001$). In contrast, preincubation with TEA

(10 mM) or INDO (5 μ M) did not significantly affect the vasodilation effect of 6-gingerol (Figure 3).

Effect of 6-gingerol on NO generation

Incubation of the isolated diabetic aortae in media containing 6-gingerol (10^{-3} M) for 3 minutes produced significant

NO generation in a dose-dependent manner (Figure 4A) and to a level similar to that induced by ACh (10^{-3} M; both at $P<0.05$ compared with control; Figure 4B). High drug concentrations were used in these experiments in order to provide an adequate signal-to-noise ratio in the NO assay.

Effect of 6-gingerol on AGE

Incubation of BSA with ribose increased AGE significantly ($P < 0.001$), as assessed by fluorimetry. This increased level of AGE was significantly ($P < 0.001$) ameliorated when incubated with AG (1 mM, as positive control), while there was no effect when incubated with different concentrations of 6-gingerol (Figure 5).

Discussion

To our knowledge, this is the first study to investigate the vasorelaxant mechanism of 6-gingerol, the main constituent of ginger, in diabetic aortae. The results show that the enhanced α -adrenergic responsiveness of aortic rings from diabetic animals was significantly attenuated by 6-gingerol. This inhibition was concentration dependent with a maximum effect at 3 μ M. The observed alleviation of exaggerated vasoconstriction and the possible mechanism associated with diabetes may be explained based on the following results of the current study: 1) 6-gingerol induced significant relaxation of PE-precontracted aortae, 2) the observed relaxation was significantly inhibited by the NO synthase inhibitor L-NAME and the guanylate cyclase inhibitor MB, and 3) 6-gingerol stimulated NO generation from the isolated aortae. These findings provide convincing evidence that 6-gingerol offsets the exaggerated vasoconstriction in diabetic aortae through NO-dependent mechanism. The use of 6-gingerol as a complementary medicine in diabetes may help to ameliorate the associated vascular complications.

Increased vascular responsiveness to contractile agents in STZ-diabetic rats has been reported in most of the previous studies,²²⁻²⁴ which strongly supports the use of the diabetic model in the current study with regard to vascular abnormalities. Alternatively, some studies reported unchanged²⁵ or reduced²⁶ vascular response to α -adrenergic agonists, which could possibly be explained by the use of low PE concentrations²⁵ or the nonspecific adrenergic agonist noradrenaline.²⁶

In addition, attenuated relaxation responses to ACh were observed in the current study in STZ-diabetic aorta, in

Figure 5 Effect of 6-gingerol (10^{-6} to 10^{-3} M) on the generation of advanced glycation end products (AGEs).

Notes: Bars show mean \pm SEM of $n=3$. ***Significantly ($P<0.001$) different from BSA group. ###Significantly ($P<0.001$) different from BSA-ribose group.

Abbreviation: SEM, standard error of the mean.

agreement with the findings of Orie et al.²⁷ In STZ-induced DM, basal levels of NO production and expression of eNOS are reduced in diabetic arteries.²⁸ In the present study, the exaggerated vasoconstriction seen in diabetic aortae was significantly attenuated with short-term in vitro incubation with 6-gingerol in a concentration-dependent manner, while the impaired relaxation was not affected.

Because of its pivotal role in the development of cardiovascular complications,²⁹ the effect of an AGE metabolite (MG) on vascular contractility and the possible effect of 6-gingerol were investigated. The current study shows that the aortic rings incubated with MG showed an enhanced contractile response to PE similar to diabetic aortae, and this enhanced effect was significantly ameliorated with 6-gingerol. This is in accordance with the reported inhibition of NO availability by AGE in human endothelial cells.³⁰ In contrast, the relaxation response to ACh was significantly attenuated when the aortic rings were incubated with MG. This is in accordance with the results of Vlassara et al.,³¹ who showed that administration of AGE-modified albumin to nondiabetic rats or rabbits markedly impairs vasodilatory responses to ACh. In the present study, incubation with 6-gingerol significantly alleviated the exaggerated vasoconstriction in the aortae exposed to MG, but did not affect the impaired relaxation.

The mechanism(s) by which 6-gingerol alleviates vasoconstriction of diabetic aortae could be mediated by direct vasodilation through NO generation and stimulation of GC. In the present study, 6-gingerol induced significant relaxation of PE-precontracted aortae. This is in agreement with the

reported antihypertensive effect of ginger aqueous extract and its phenolic constituents in rats.³² The observed vasodilation seems to be through stimulating NO generation from the vasculature as it was significantly inhibited by the NOS inhibitor and the GC inhibitor, while not affected by the calcium-activated potassium channel blocker or the cyclooxygenase inhibitor INDO. In support of this, we found that 6-gingerol stimulated similar amounts of NO generation to those by ACh. In contrast, incubation with 6-gingerol did not affect AGE formation. This suggests that the observed alleviation of exaggerated vasoconstriction by 6-gingerol due to MG incubation is through inhibiting the effects of AGE on the blood vessels rather than affecting AGE formation. This is consistent with the reported decrease in the soluble receptor for AGE induced by 6-gingerol in doxorubicin-treated rats.³³

Conclusion

The current study showed that 6-gingerol ameliorates enhanced vascular contraction in diabetic aortae, which may be partially attributed to the vasodilation effect of 6-gingerol through stimulation of aortic NO generation.
