**Objectives:** The etiology of depression remains unknown. There is, however, a growing body of evidence that cytokines are involved in the pathophysiology of depression. The aim of this study is to investigate the effects of fluvoxamine on plasma interleukin-6 (IL-6) levels and on clinical improvement of the depressive state.

**Subjects and methods:** Thirty patients who met the *DSM-IV* criteria for major depressive disorder (MDD) were enrolled in the study. Thirteen were male and 17 were female, and their ages ranged from 26 to 70 years (mean  $\pm$  standard deviation  $45.0 \pm 14.2$ ). The patients were treated with fluvoxamine for 8 weeks. The dosages of fluvoxamine varied among the patients and, based on ethical considerations, were not fixed.

**Results:** The fluvoxamine doses were positively related to plasma fluvoxamine levels ( $r=0.8798$ ,  $P<0.001$ ). A significant correlation was observed between the patients' plasma IL-6 levels and their 17-item Hamilton Rating Scale for Depression (HAM-D17) scores ( $r=0.4555$ ,  $P=0.0010$ ). A positive correlation was found between the delta plasma IL-6 (week 0–week 8) and the delta HAM-D17 (week 0–week 8) ( $r=0.5226$ ,  $P=0.002$ ).

**Conclusion:** Effect of fluvoxamine on IL-6 is partially associated with its clinical efficacy for MDD.

**Keywords:** fluvoxamine, interleukin, Hamilton Rating Scale for Depression, major depressive disorder

## Introduction

Selective serotonin reuptake inhibitors (SSRIs) are the first-line treatment for major depressive disorder (MDD).<sup>1</sup> SSRIs work on the serotonin transporter (SET), and Coleman et al<sup>2</sup> recently used X-ray crystallography to determine two structures of the SET that were bound to an SSRI. Serotonin might play an important role in the pathophysiology of MDD. However, the etiology of depression remains unknown. There is a growing body of evidence that cytokines are involved in the pathophysiology of depression.<sup>3,4</sup> Activated microglia exhibit increased production of inflammatory cytokines (eg, interleukin (IL)-1 $\beta$ , tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and IL-6).<sup>3</sup> According to the recent meta-analysis, levels of two cytokines (IL-6 and TNF- $\alpha$ ), one soluble cytokine receptor and one cytokine receptor antagonist were significantly increased in acutely ill patients with MDD compared with controls.<sup>5</sup> Another former meta-analysis demonstrated that a significantly higher concentrations of the proinflammatory cytokines TNF- $\alpha$  and IL-6 in depressed subjects compared with control subjects.<sup>6</sup> Antidepressant treatment also reduced levels of IL-1 $\beta$  and possibly those of IL-6.<sup>7</sup> It is well-known that noradrenaline stimulates the release of cytokines from

microglia and macrophages, and the effect of noradrenaline and cytokines is regulated by adrenoceptors.<sup>3</sup> We reported that the plasma levels of IL-6 are raised during depressive periods.<sup>8,9</sup> According to a meta-analysis<sup>7</sup>, treatment with antidepressants reduced the serum IL-6 levels in patients with MDD. In other words, plasma IL-6 is a state marker of major depressive episodes. To the best of our knowledge, there are no reports of investigations into the responses to fluvoxamine, an SSRI, and plasma IL-6 levels in patients with MDD. Thus, this study examined the responses to fluvoxamine and plasma IL-6 levels in MDD patients. An activation of the immune system has repeatedly been described in MDD, and it has been suggested that the cytokines play a key role in this immune activation.<sup>3,4</sup> Within the brain, cytokines exert various effects on neurotransmitters – especially the noradrenaline systems, which are thought to play a pivotal role in psychiatric disorders.<sup>3</sup> IL-6 receptors are widely distributed in the brain, especially in the hippocampus and hypothalamus.<sup>10</sup> Maes<sup>11</sup> demonstrated that the plasma concentrations of IL-6 were significantly higher in MDD subjects than in healthy controls. This finding has been confirmed by a number of subsequent meta-analyses.<sup>12</sup> The above findings suggested that IL-6 might play a role in the pathogenesis of MDD. From the above findings, it may be surmised that IL-6 may play a role in the biology or somatic consequences of MDD. Fluvoxamine is an SSRI that is widely used in the treatment of depression and other psychiatric disorders including anxiety disorders, and it has been suggested to have early effects when used as an antidepressant drug.<sup>13,14</sup> In addition, the results of a recent meta-analysis also suggest that treatment with fluvoxamine leads to symptomatic improvements in patients with MDD by the end of the first week of use.<sup>15</sup>

The aim of this study is to investigate the effects of fluvoxamine on plasma IL-6 levels, especially focusing on the dose or plasma level of fluvoxamine and the clinical improvement of the depressive state.

## Subjects and methods

Thirty patients who met the *DSM-IV* criteria (American Psychiatric Association, 1994) for MDD without other Axis I or Axis II disorders were enrolled in the study. Thirteen were male and 17 were female, and their ages ranged from 26 to 70 years (mean  $\pm$  standard deviation =  $45.0 \pm 14.2$ ). All patients were physically healthy and free of current alcohol and/or drug abuse. The patients were treated with fluvoxamine for 8 weeks. The dosages of fluvoxamine varied among the patients and, based on ethical considerations, were not fixed.

Depressive symptoms were evaluated using the 17-item Hamilton Rating Scale for Depression (HAM-D17).<sup>16</sup> The patients' baseline blood samples drawn into heparinized tubes were obtained before breakfast at 08.00–10.00 prior to the initiation of SSRI treatment. None of the patients took any medications for at least a month before the blood samplings. The plasma samples were quickly separated in a centrifuge and stored at  $-80^{\circ}\text{C}$  until they were assayed.

The plasma levels of IL-6 were measured with our quantitative sandwich enzyme assay technique, which we previously described using a Quantikine<sup>®</sup> HS High Sensitivity Immunoassay kit (R&D Systems, Minneapolis, MN, USA).<sup>17</sup> The standard curve was linear from 0.1 to 10 pg/mL, and the detection limit was 0.1 pg/mL. The intra- and interassay coefficients of variation were 7% and 9%, respectively. The recovery rates of the exogenously added IL-6 in the measured plasma samples were  $>95\%$ .

The protocol of this study was approved by the Ethics Committee of the University of Occupational and Environmental Health, Kitakyushu, Japan. Written informed consent was obtained from all subjects. The plasma fluvoxamine level was measured using high performance liquid chromatography according to the method we previously described.<sup>18</sup> In brief, 1 mL of plasma alkalized with 500  $\mu\text{L}$  of 2 M sodium hydrogen carbonate was extracted by hexane (10 mL) after the addition of the internal standard (clomipramine). Shaken horizontally for 20 min and then centrifuged at  $2,000 \times g$  for 10 min, the upper organic layer was removed and dried under  $\text{N}_2$ . After being dissolved in 200  $\mu\text{L}$  of mobile phase, a 50  $\mu\text{L}$  aliquot of the final preparation was subjected to high performance liquid chromatography. All experiments were performed in triplicate.

## Statistical analysis

Since the data were normal distributed using Kolmogorov–Smirnov test. A paired *t*-test was used to compare the plasma IL-6 levels and the HAM-D17 scores between at week 0 and at week 8. Relationships between two variables were examined using Pearson's correlation coefficients. The level of significance for all analyses was set at  $P < 0.05$ .

## Results

1) The demographics of each group are given in Table 1; 2) the fluvoxamine dose was positively related to the plasma fluvoxamine level (Pearson's correlation coefficients;  $r = 0.8798$ ,  $P < 0.001$ ; Figure 1); 3) plasma IL-6 levels decreased from week 0 ( $134 \pm 53$  pg/mL) to week 8

**Table 1** Demographics of participants

M (F)	13 (17)
Age (years)	45.0±14.2
First/recurrent	12 (18)
Duration of illness	9.4±3.6 (weeks)
Fluvoxamine dose (max)	111.2±37.4 (mg/day)
HAMD17 (at week 0)	24.1±3.1
HAMD17 (at week 8)	12.2±2.8

(106±34 pg/mL; paired Student's *t*-test,  $P=0.0183$ ); 4) the HAMD17 scores decreased week 0 (24.4±3.1) to week 8 (12.2±2.8; paired *t*-test,  $P=0.0001$ ); 5) a significant correlation was observed between the patients' plasma IL-6 levels and their HAMD17 scores (Pearson's correlation coefficients;  $r=0.4555$ ,  $P=0.0010$ ; Figure 2); 6) a positive correlation was found between the delta plasma IL-6 (week 0–week 8) and the delta HAMD17 (week 0–week 8) (Pearson's correlation coefficients;  $r=0.5226$ ,  $P=0.002$ ; Figure 3); 7) no correlation was found between plasma fluvoxamine level at week 8 and the delta HAMD17 (Pearson's correlation coefficients;  $r=1.3045$ ,  $P=0.2020$ ; Figure 4); 8) no correlation was observed between delta plasma IL-6 (week 0–week 8) and plasma fluvoxamine level at week 8 (Pearson's correlation coefficients;  $r=0.2982$ ,  $P=0.7676$ ; Figure 5).

## Discussion

The main finding of this study was that a positive correlation was observed between the delta plasma IL-6 and the delta HAMD17 in MDD patients treated with fluvoxamine. This indicates that fluvoxamine an association exists between the decrease in plasma IL-6 and the clinical improvement of depressive symptoms. We also demonstrated that the plasma IL-6 level was associated with the severity of depressive symptoms evaluated by HAMD17. Recently, we reported that

**Figure 1** Fluvoxamine dose and plasma fluvoxamine concentration.  
**Notes:**  $r=0.8798$ ,  $P<0.001$ .

**Figure 2** Baseline (week 0) HAMD17 and baseline (week 0) plasma IL-6 concentration.

the baseline plasma IL-6 levels were significantly higher in responders to paroxetine or sertraline than in nonresponders. In that study, a significant positive correlation was observed between the patients' HAMD17 scores and the baseline plasma IL-6 levels. We reconfirmed in this study that plasma IL-6 reflects the severity of major depressive episodes. Taking all of these findings into account, it is possible that plasma IL-6 is a biological state marker for MDD.

IL-6 has been proposed to be involved in the pathology of MDD.<sup>18</sup> In particular, it was suggested that IL-6 is involved in multiple physiological systems, including the hypothalamic-pituitary-adrenal axis, corticotrophin-releasing hormone activity at limbic sites, noradrenaline utilization, the release of oxidative stress, the apoptotic pathways, and kinase signaling,<sup>19–22</sup> all of which have very close relationships to the pathophysiology of MDD. Li et al<sup>23</sup> recently showed that noradrenaline significantly increased the mRNA and protein expression of IL-6 in

**Figure 3** The change in plasma IL-6 concentration and the change in HAMD17.

U937 macrophages in time- and concentration-dependent manners. The  $\beta$ -adrenoreceptor inhibitor propranolol blocked noradrenaline-induced IL-6 expression in the mRNA and protein levels in U937 macrophages, which hypernoradrenergic activity promotes IL-6 production. Actually, we reported that plasma 3-methoxy-4-hydroxyphenylglycol, a major metabolite of noradrenaline, was higher in the subgroup of MDD patients than in healthy control subjects, and also demonstrated that fluvoxamine decreased the plasma 3-methoxy-4-hydroxyphenylglycol level, which was associated with the clinical improvement of depressive symptoms.<sup>24</sup> Li et al<sup>23</sup> reported that the MHPG levels were elevated with anxiety, agitation, and insomnia, and the authors clonidine, an  $\alpha$ 2-adrenoceptor agonist, was effective for certain depressive symptoms. Therefore, suppressing noradrenaline activity enhanced the serotonergic functions by fluvoxamine leads to weaken IL-6 production in MDD patients. In other words, fluvoxamine increases brain serotonin, and increased

**Figure 5** The change in plasma IL-6 concentration and plasma fluvoxamine concentration at week 8.

**Abbreviation:** IL-6, interleukin-6.

serotonin stimulates the  $\alpha$ 2-adrenoreceptor, which reduces noradrenergic activity.<sup>25</sup> In short, an interaction exists between noradrenergic neurons and serotonergic neurons.

Microglia are the primary central reservoirs of proinflammatory cytokines, and they act as antigen-presenting cells in the brain.<sup>26</sup> Although it is uncertain whether peripheral IL-6 levels represent the levels found in the brain, evidence suggests that IL-6 crosses the blood–brain barrier, and the peripheral level might represent an overflow from the central nervous system and may be a marker of an inflammatory process in the brain.<sup>27</sup>

A linear relationship was found between the dose and plasma concentrations of fluvoxamine. No association was found, however, between plasma fluvoxamine level and the delta HAMD17. These results suggest that the dose and plasma levels of fluvoxamine independently influenced the clinical improvement of depressive symptoms. Pharmacodynamic factors and pharmacokinetic factors are both important for the clinical efficacy of fluvoxamine in MDD. Since placebo control group was not prepared, the possibility remains that reduction of plasma IL-6 levels might be related to recovery itself, and do not necessarily have to be a pharmacological effect of fluvoxamine.

## Limitations

One limitation of this study was that the sample size was small and heterogeneous, not reference group, not placebo group, which might be associated with a type I or type II error. The fact that the dosage of fluvoxamine was not fixed is another problem. Thus, further research using larger sample with reference group, a different antidepressant, is needed to test the preliminary results achieved in this study.

## Conclusion

The effect of fluvoxamine on IL-6 is related to its clinical efficacy of fluvoxamine for MDD. We should, however, be cautious for interpreting the preliminary results.

## Acknowledgment

The study was supported by a Health and Labor Research grant (#1401010101).
