Abstract: Umbelliferone β -D-galactopyranoside (UFG), isolated from plants, exhibits promising inhibitory action on numerous diseases. The present research was initiated to develop a suitable delivery system for UFG with an intention to enhance its therapeutic efficacy against diethyl nitrosamine (DEN)-induced hepatocellular carcinoma (HCC) in Wistar rats. UFG-loaded polymeric nanoparticles prepared by sonication were scrutinized for average size, drug loading capacity, zeta potential, and drug release potency in animals. HCC cell lines HuH-7 and Hep G2 were used for in vitro cytotoxic investigation. Several hepatic, nonhepatic, antioxidant, and anti-inflammatory biochemical parameters were estimated to establish the anticancer potential of UFG nanoformulation. Microscopical and histopathological investigations were also undertaken to substantiate the results of our work. Umbelliferone β -D-galactopyranoside-loaded poly(D,L-lactide-co-glycolide) nanoparticles (UFG-PLGA-NP) with particle size of 187.1 nm and polydispersity index 0.16 were uniform in nature with 82.5% release of the total amount of drug after 48 h. Our study successfully established the development and characterization of UFG-PLGA-NP with noticeable effect against both in vivo and in vitro models. The anticancer potential of UFG-PLGA-NP was brought about by the management of DEN-induced reactive oxygen species generation, mitochondrial dysfunction, proinflammatory cytokines alteration, and induction of apoptosis. Positive zeta potential on the surface of UFG-PLGA-NP would have possibly offered higher hepatic accumulation of UFG, particularly in the electron-dense mitochondria organelles, and this was the take-home message from this study. Our results demonstrated that such polymer-loaded delivery systems of UFG can be a better option and can be further explored to improve the clinical outcomes against hepatic cancer.

Introduction

Hepatocellular carcinoma (HCC) is one of the leading risks to human health, the fifth most common cancer worldwide, and is ranked third in causing cancer-related deaths. Hepatitis C virus,¹ hepatitis B virus,² Aflatoxin B₁, and diethyl nitrosamine (DEN) are the prime risk factors for HCC.³ Past efforts have brought very small success in treatment of HCC patients. The available option for treatment of HCC is liver transplantation and surgical resection, which can only be beneficial for patients where early detection or diagnosis is made to detect this disease. Hormonal therapy, radiotherapy, and immune-chemotherapy are the other options for HCC treatment but

with limitations like tumor shapes, type, number, stage, and vascular movement along with patient's medical history for successful outcome. These therapies are always accompanied by higher toxicity and drug resistance and generally affect the normal cells along with cancer cells. The related side or adverse effects such as diarrhea, thrombocytopenia, constipation, alopecia, and nausea overshadow the treatment and debilitate the patient. The limitations of the drugs currently available for HCC keyed the researchers to take new approach for higher clinical efficacy with minimized side effects.⁴ Therefore, researchers have become more focused on natural drugs for cancer prevention including the treatment of HCC. In this effort, some natural compounds showed promising results with striking success in preclinical setup, but poor bioavailability and systemic toxicity were the major hurdles.⁵ Various experimental and clinical studies have proved the importance of free radical scavenger-rich food that can reduce or minimize the chronic diseases, especially cancer. 7-hydroxycoumarin (umbelliferone) already proved for its antidiabetic, anti-inflammatory, and antinociceptive effect via free radical scavenging along with positive potential on arthritis, laryngeal cancer, renal cancer, and airway inflammation. These major breakthroughs revoked us to make an effort in evaluating umbelliferone for its anticancer effect against DEN-induced HCC.

Although it is well documented that umbelliferone has significant effect in restricting the proliferation and cytotoxic potential in liver cells, no study was undertaken for its nanoformulation. Nanoformulation provides an alternative form of drug delivery system, which attributes to the feasibility of incorporating hydrophilic and hydrophobic molecules, better cellular uptake, and long shelf-life of molecules.^{6,7} Poly(D,L-lactide-co-glycolide) (PLGA) is a biodegradable polymer, regularly used as a biomaterial for its outstanding biocompatibility, along with its use in drug delivery systems, including films, blends, microspheres, matrixes, pellets, and nanoparticles, to name few.⁸ Various studies have showed that polymeric nanoparticles of naturally occurring compounds, namely, curcumin and quercetin, have enhanced significant chemopreventive potential against various disorders.^{7,8} Hence, it was thought to be worth scrutinizing the effectiveness of umbelliferone β -D-galactopyranoside (UFG) and its polymeric nanoparticles formulation in combating DEN-induced hepatocarcinogenesis.

Materials and methods

Chemicals and equipments

UFG was isolated by Kumar et al^{9,10} All the chemicals and reagents used for the preparation of formulation were

procured from Hi media, India. The polydispersity index (PDI) and particle size (PS) of the nanoformulation were determined using the Zeta Size Nao ZS (Malvern Instruments Limited, Worcestershire, UK). The LEO 435 V scanning electron microscopy (SEM) (Leo Electron Microscopy Ltd., Cambridge, UK) and transmission electron microscopy (TEM) CM-10 (Philips, the Netherlands) were used for the microscopical analysis of formulation. Radioactivity was measured by a gamma ray spectrometer (GRS23C, Electronics Corporation of India Limited, India).

Formulation of UFG polymeric nanoparticles

Double emulsion solvent techniques with minor modification were used for the preparation of polymeric nanoparticles by Perlatti et al.¹¹ Dispersing agents Tween 80 and Span 60 were employed for the development of internal and external aqueous phase with polyvinyl alcohol (PVA) as external aqueous phase and stearic acid as the stabilizing agent. Primary emulsion was sonicated by an ultrasonicator under ice-cool bath for 15 s, just to prevent the elevation of temperature, and the resultant mixture was gradually deionized by PVA solution (5 mL) with or without surfactant (Tween 80) in various concentrations. The above mixture was again sonicated for 15 s for secondary emulsion ($W_1/O/W_2$) with continuous stirring at 1,200 rpm for complete evaporation of dichloromethane. Residual surfactants and free drug were removed from polymeric nanoparticles by successive washing. Nanoparticles were stabilized by dispersing them in a low volume of water and lyophilized for 24 h. A similar protocol was followed for blank nanoparticles and control group, and were kept at -20°C for further use (Figure 1).

Optimization of formulation parameters using Box–Behnken design (BBD)

Drug loading (DL) concentration, PLGA polymer concentration, and sonication time were analyzed for umbelliferone β -D-galactopyranoside-loaded PLGA nanoparticles (UFG-PLGA-NP). Formations of polymeric nanoparticles were evaluated for the above factors with the use of response surface methodology using BBD and Design Expert Software 8.0.7.1. All the experiments were performed in triplicate. Seventeen runs were performed with three independent factors (DL, polymer concentration, and sonication time) from BBD to obtain a three-level factorial design of experiments (Table 1). Response surface and contour plots were generated for better understanding of interaction between the response variables and the independent factors. Numerical and graphical optimizations were performed to

Figure 1 Schematic representation of development of umbelliferone β -D-galactopyranoside polymeric nanoformulation.

Abbreviations: BSA, bovine serum albumin; DCM, dichloromethane; PLGA, poly(d,l-lactide-co-glycolide); PVA, polyvinyl alcohol.

determine the optimum conditions for preparation of UFG-PLGA-NP and the predicted values of desired responses.

Characterization of UFG-PLGA-NP

Estimation of PS and PDI of UFG-PLGA-NP

PS and PDI of UFG-PLGA-NP were analyzed by Zetasizer (Nano-ZS, Malvern Instruments). The prepared UFG-PLGA-NP were harvested and washed with deionized water to remove free drug, free polymer, and surfactants. The particles were dispersed in a low volume of water and lyophilized for 24 h to obtain powder and stable nanoparticles. The prepared formulation was kept at -20°C . Estimation of PS and PDI was made by diluting the nanoformulation with deionized water (200 times) followed by constant shaking to obtain about 100–250 kilo counts per second. Dynamic

light scattering technique was used for the determination of PDI and PS of the UFG-PLGA-NP.

Release of UFG-PLGA-NP

Dialysis technique was employed to determine the release of UFG-PLGA-NP by phosphate buffer (pH=7.4). The aliquots obtained at each point of time were analyzed for drug released as a function of time.

Entrapment efficiency and DL of UFG-PLGA-NP

The loading capacity and entrapment efficiency (EE) of UFG-PLGA-NP were estimated by separating free UFG from the PLGA-NP at 11,000 rpm for 30 min centrifugation. The free UFG present in the supernatant was quantified

Table 1 Effect of UFG-PLGA-NP treatment on the liver parameters in DEN-induced carcinogenesis in rats

S no	Groups	Initial body weight (g)	Final body weight (g)	Liver weight (g)	Relative liver weight (g liver/100 g body weight)	iPH	PG

Notes: DEN control group compared with normal control group. #### P <0.001 is considered as extremely significant and the treated groups compared with the DEN control. * P <0.05 is considered as significant, ** P <0.01 is considered as very significant, *** P <0.001 is considered as extremely significant. Statistical analysis was performed by one-way analysis of variance followed by the Dunnett's test. Data presented as mean \pm SD.

Abbreviations: DEN, diethyl nitrosamine; iPH, ponderal homogeneity index; PG, ponderal grain; PLGA, poly(d,l-lactide-co-glycolide); S no, serial number; UFG, umbelliferone β -D-galactopyranoside; UFG-PLGA-NP, UFG-loaded PLGA nanoparticles.

through high-performance liquid chromatography. The EE and DL capacity of the UFG-PLGA-NP were calculated by calculating the difference between the initial amount of UFG used in formulation and the amount of UFG present in supernatant after centrifugation at 21 g rpm for 30 min at 10°C. EE of the PLGA-NP was determined by the following formula:

$$EE (\%) = \frac{\text{Total amount of UFG} - \text{Amount of UFG in total supernatant}}{\text{Amount of UFG}} \times 100$$

SEM and TEM of UFG-PLGA-NP

During the SEM analysis, a small quantity of UFG-PLGA-NP was mounted on an aluminum sample, which was sputter-coated with gold-palladium alloy to reduce the surface charge. LEO 435 V (SEM) (Leo Electron Microscopy Ltd., Cambridge, UK) was used at a 155 mm working distance and 15 kV accelerating voltage.

Microscopical evaluation was carried by TEM CM-10 (Philips, the Netherlands). In brief, one drop of UFG-PLGA-NP formulation was placed on a carbon-coated grid with 2% phosphotungstic acid and left for 30 s. The coated dried grid was mounted on the slide and observed.

In vitro studies

Assessment of growth inhibition in HCC cell lines

Cell lines storage and culture conditions

HCC cell lines HuH-7 and Hep G2 were established by the method reported by Farmer et al.⁴ The cells were cultured by Dulbecco's Modified Eagle's Medium and maintained in an incubator with CO₂ with constant humidity. The sensitivity of UFG was determined in both the cell lines.

Preparation of various dilutions of UFG

The solution of UFG was prepared with serial dilution, mixed with media to obtain the various concentrations of UFG in solution with application of it on growing adherent cells. The dose of the UFG ranging from 0.1 to 50 mM was selected for the in vitro anticancer activity.

Estimation of growth inhibition

Viable cell counting

The effect of UFG was evaluated on cells by direct counting. Both cell lines (HuH-7 and Hep G2) were seeded into plates (60 mm) with different concentrations of UFG loaded on culture media. After 48 h, trypan blue dye exclusion was used for counting the floating and adherent cells. The enhancement of relative rate of cell counts in the presence of ligands was

compared with control (without drug) to give the considerable representation of cell growth.

Estimation of DNA synthesis

³H thymidine incorporation was used for determination of DNA synthesis. Briefly, the cells were harvested into 24-well plates in complete culture media, with various concentrations of UFG in media.⁴ After 24 h, 1 μCi (methyl-³H)-thymidine was mixed in each well and incubated for 6 h. The cells were harvested by glass fiber filter mats and dried for 1 h. The level of ³H thymidine incorporation was estimated by 1450 Microbeta™ scintillation counter (Wallac Oy, Finland).

Animals

Swiss Albino Wistar (100–130 g, male) rats were used for the current experimental study. The rats were caged in the animal house under the standard temperature (23°C±5°C; 60%±5% relative humidity) with 12:12 h light and dark cycle. The experimental animals were on standard pellet diet and water *ad libitum*. The entire protocol was approved by the Institutional Animal Ethical Committee (IAEC) and all of the study was performed in accordance with the guidance of Committee for the Purpose of Control and Supervision of Experiments on Animals, Ministry of Social Justice and Empowerment, Government of India. The current study was approved by the Laboratory Animal Facility, Sam Higginbottom University of Agriculture, Technology & Sciences, Allahabad (IAEC/SHIATS/PA151X/FVK01).

Experimental design

Rats were randomly selected in six groups, which received carcinogen with tested drug as per their individual body weights depicted below.

- Group I: Normal control (untreated controls and received the three doses of olive oil with regular interval between doses)
- Group II: Normal control + UFG (50 mg/kg)
- Group III: DEN control
- Group IV: DEN + UFG (5 mg/kg)
- Group V: DEN + UFG (50 mg/kg)
- Group VI: DEN + UFG-PLGA-NP (containing the 5 mg/kg UFG).

Group III–VI rats were treated intraperitoneally with three doses of DEN (200 mg/kg, body weight). All the concerned group rats received the oral administration of various doses of UFG and UFG-PLGA-NP, respectively. At the end of the experimental study (22 weeks), the final body weight of rats was estimated, blood collected from the retro-orbital route, liver tissue was excised, cleaned with ice-cold saline, and

further blotted to dryness. It was homogenized with 0.1 M phosphate buffer saline (pH =7.4) and subjected to high-speed centrifugation to obtain clear supernatant component. The clear supernatant was further used for the estimation of biochemical parameters.

Biochemical parameters

All the hepatic biochemical parameters including aspartate amino transferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase (ALP) were estimated by standard kits (Span Diagnostic Lab). The serum α -feto protein (AFP) was determined using the reported method of Anwar et al.⁶ Nonhepatic parameters, namely, total protein, albumin, total bilirubin, and gamma-glutamyl transpeptidase (GGPT), were also estimated by standard reported methods.¹¹⁻¹⁴

Hematological parameters

The hematological parameters such as red blood cells (RBC), erythrocytes sedimentation rate (ESR), white blood cells (WBC), and hemoglobin (Hb) were estimated using the method reported by Kumar et al.^{15,16}

Antioxidant parameters

Antioxidant parameters were estimated from liver homogenates such as catalase (CAT), lipid peroxidation (LPO), superoxide dismutase (SOD), glutathione transferase (GST), glucose 6-phosphate dehydrogenase, conjugated dienes (CD), and glutathione peroxidase (GPx) by standard methods.

Estimation of proinflammatory cytokines

The proinflammatory cytokines interleukin-1 β (IL-1 β), tumor necrosis factor- α (TNF- α), and IL-6 were estimated by kits of enzyme-linked immunosorbent assay as per the manufacturer's instruction.

Isolation and autopsy of tissue

After 22 weeks of treatment, all rats were sacrificed. After postpartum, liver was excised immediately, cleaned, washed, and rinsed in ice-cold normal saline solution (until bleached of blood) and blotted dry on filter paper to remove blood. A small representative portion of liver (~5 mm thick) was fixed in 10% formalin and stored at 4°C.

Statistical analysis

Design Expert Software was used for the optimization of various independent variables. All the values of in vitro experimental results were represented as mean \pm standard deviation (SD), while in vivo results were shown as mean \pm

standard error of mean. Statistical analysis was performed by GraphPad Prism one-way analysis of variance (ANOVA) followed by the Dunnett's test.

Result

Physicochemical characteristics of UFG-PLGA-NP

The physicochemical characteristics were defined in terms of PDI, PS, and EE of UFG-PLGA-NP and are summarized in [Table S1](#). TEM and SEM output clarifies that the nanoformulation of UFG-PLGA-NP has regular shape, smooth surface, and PDI, which confirms uniform size distribution. Zeta potential results indicate the stable polymeric NP of UFG-PLGA-NP. In vitro release study illustrated a biphasic pattern with an initial burst during the first 4 h, followed by slow and sustained release of UFG-PLGA-NP.

Characterization and optimization of UFG-PLGA-NP

Optimization of polymeric nanoformulation of UFG was performed by PDI and PS distribution. The actual and predicted data for PDI and PS are tabulated in [Table S2](#). The data were generated, scrutinized by the design expert software, and predicated for PS, PDI, and EE.

Final equation regarding coded factors for particle size

$$PS = + 184.18 + 37.86* A - 65.85* B - 11.78* C + 2.55* AB + 5.20* AC + 0.25* BC + 102.48* A^2 + 76.07* B^2 - 26.18* C^2$$

Final equation regarding coded factors for PDI

$$PDI = + 0.20 + 0.041* A - 0.084* B - 0.022* C - 0.013* AB - 0.037* AC - 2.500E - 004* BC + 0.11* A^2 + 0.092* B^2 - 0.044* C^2$$

Final equation regarding coded factors for EE

$$EE = + 86.56 - 3.63* A + 13.05* B + 0.57* C + 1.57* AB - 0.69* AC + 0.59* BC - 7.22* A^2 - 11.10* B^2 + 0.36* C^2$$

Three-dimensional response surface (B, D, and F) and contour plots (A, C, and E) illustrate the effects of polymer concentration (A), drug percentage (B), and sonication

time (C), and the effect of the reciprocal interaction of the dependent variables of the UFG formulation is represented in [Figure S1](#) (PDI), [Figure S2](#) (PS), and [Figure S3](#) (EE), respectively. The ANOVA of the model for PS and PDI is presented in [Table S2](#). Point prediction of design expert software was used to determine the optimum values of formulation factors for PDI and the smaller PS of UFG-PLGA-NP.

In vitro release of UFG-PLGA-NP

The in vitro release study demonstrated the total amount of drug released after 48 h, which was found to be 82.5%. The release pattern confirmed the controlled and sustained-release study of UFG-PLGA-NP ([Figure S4](#)). Figure 2 represents the PS distribution of UFG-PLGA-NP.

UFG induced growth inhibition

The treatment of UFG on both cell lines after 48 h showed the significant reduction in the relative increment of cell number at concentrations of 10, 25, and 50 μM (Figure 3A).

UFG inhibited DNA synthesis

It was confirmed by estimation of ^3H thymidine incorporation in both types of cell lines. Figure 3B confirmed that the UFG significantly inhibited the ^3H thymidine incorporation in a dose-dependent manner for both cell lines.

Animal growth, food, and water intake

Swiss albino Wistar rats were used for the evaluation of hepatocarcinogen effect induced by DEN on liver. However, during the experimental period, none of the rats showed any external sign of disease, except that the environmental cage enrichment to prevent aggressive behavior, sporadic injuries, and focal loss of hair was reported.

Table 1 represents body weight iPH and PG for the rats of all groups. Normal control group rats showed more water and food consumption as compared to DEN-exposed groups (data not shown). The level of water consumption and food between the normal control and DEN control was not statistically significant.

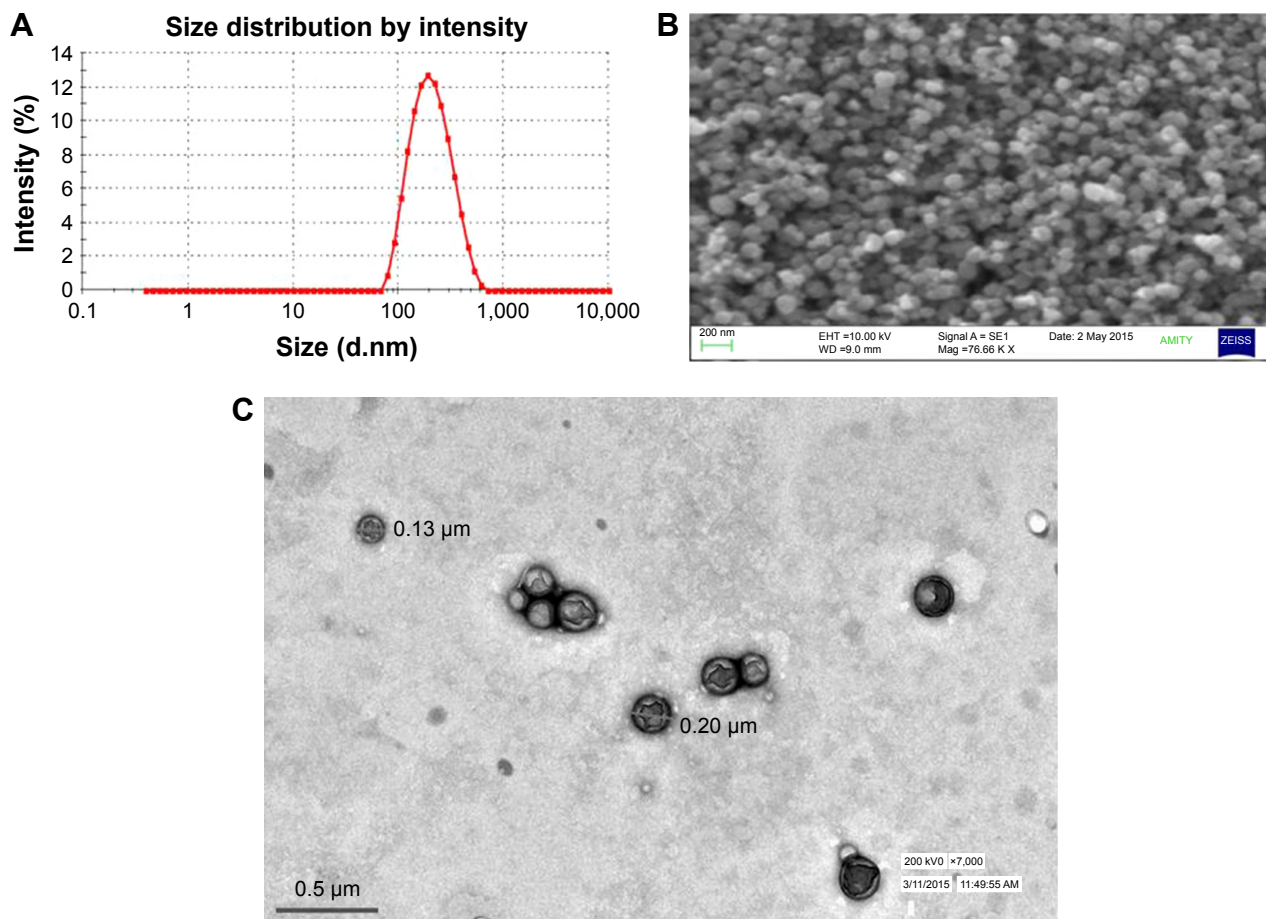

Figure 2 Particle size distribution curve.

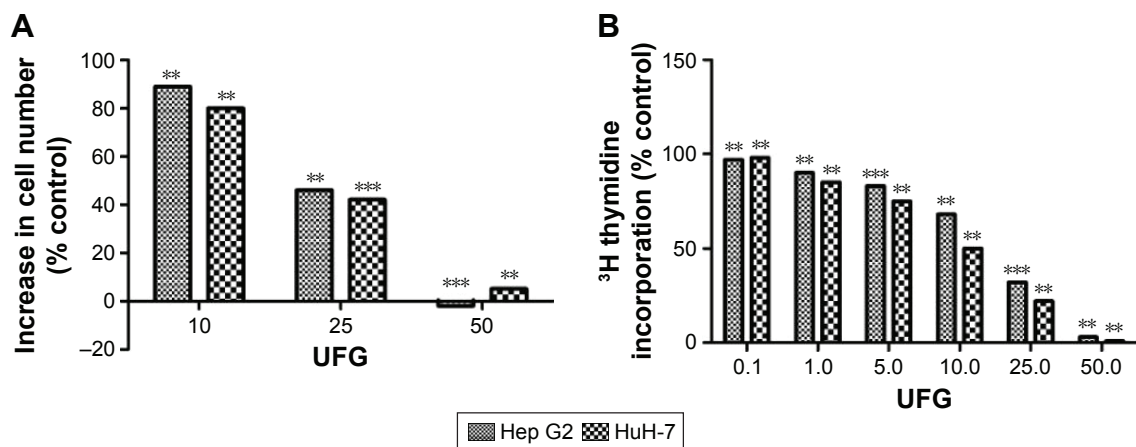

Figure 3 Effect of the UFG-PLGA-NP on Hep G2 and HuH-7 cell lines.

Notes: (A) Effect of UFG on proliferation of hepatocellular carcinoma cell lines. Cells were incubated in the presence or absence (control) of UFG, and after 48 h, total number of viable cells was counted by trypan blue dye exclusion. Increment of cell number with drugs is expressed compared with that of control. (B) UFG induced inhibition of DNA synthesis in hepatocellular carcinoma cell lines. Cells were treated with UFG in 0.1–50 μM concentration, and after 24 h, a standard ³H thymidine incorporation assay was performed. All the values are given as mean ± standard error of the mean. ** $P < 0.01$ is considered as significant; *** $P < 0.001$ is considered as very significant.

Abbreviations: UFG, umbelliferone β-D-galactopyranoside; UFG-PLGA-NP, UFG-loaded poly(d,l-lactide-co-glycolide) nanoparticles.

Effect of UFG and UFG-PLGA-NP on body weight of DEN-induced HCC rats

As shown in Table 1, the body weight of UFG and DEN group animals was significantly ($P < 0.001$) decreased as compared to normal control and normal control + UFG (50 mg/kg). The normal control group rats and normal control + UFG (50 mg/kg) group rats showed the lower liver/body weight ratio as compared to DEN control, and UFG-, and UFG-PLGA-NP-treated rats. However, the liver weight of DEN group rats was significantly higher than another group's rats.

Effect of UFG and UFG-PLGA-NP on liver nodules in DEN-induced hepatocarcinogenesis

Table S3 epitomized the total number of rats, liver nodules, nodule incidences, and an average number of nodules/nodule-bearing liver (nodule multiplicity). DEN made upsurge evident in development of hepatic nodules, while there were no visible nodules observed in the normal control and normal control + UFG (50 mg/kg) group. DEN-induced hepatocarcinogenesis rats treated with UFG declined the hepatic nodules in a dose-dependent manner. DEN-induced rats treated with UFG-PLGA-NP decreased the hepatic nodules as compared to DEN control group rats. UFG-PLGA-NP significantly declined the hepatic nodules as compared to DEN-induced control group rats (Table S4).

Effect of UFG and UFG-PLGA-NP on liver parameter

DEN made evident to boost the level of AST (155.4 ± 3.012), ALP (80 ± 2.025), ALT (133.4 ± 2.638), and AFP (71.4 ± 1.887).

DEN-induced hepatocarcinogenesis rats treated with UFG-PLGA-NP bestowed an imperative fortification in a dose-dependent manner (Figure S5).

Effect of UFG and UFG-PLGA-NP on non-liver parameters

HCC rats showed the decreased level of total protein, albumin, GGPT, and total bilirubin (Figure S6) along with the desiccated level of albumin and total protein, which implied the destitute liver functions and failure to fight infections. These rats treated with UFG-PLGA-NP significantly elevated the level of total protein, albumin, GGPT, and total bilirubin as compared to other groups of treatment. The elevated levels of total protein, albumin, and A/G indicate the reform of liver function in DEN-induced hepatocarcinogenesis.

Effect of UFG and UFG-PLGA-NP on hematological profile

We further estimated the effect of DEN and UFG on the hematological parameters such as WBC, RBC, ESR, and Hb (Figure S7). DEN control group confirmed the boosted content of WBC and ESR and reduced level of RBC and Hb, which were significantly ($P < 0.001$) restored by the UFG. However, DEN-induced rats treated with UFG-PLGA-NP significantly ($P < 0.001$) modulated the hematological profile near to the normal control group rats.

Effect of UFG and UFG-PLGA-NP on antioxidant enzymes

Diseased rats confirmed the increased level of LPO, determined in term of malonaldehyde (MDA) as compared to

normal rats. UFG treatment confirmed the dose-dependent reduction in LPO, supporting the antioxidant effect of drug. UFG-PLGA-NP group rats afforded the momentum of protection against lipid peroxides induced by DEN in hepatic tissue. The extent of CD in the hepatic tissue confirmed the increased level of CD, which was significantly ($P < 0.001$) altered by the UFG in a dose-dependent manner. In contrast, rats in the UFG-PLGA-NP-treated group showed a remarkable inhibition in the content of CD as compared to other groups. DEN treatment showed the significant ($P < 0.001$) reduced content of reactive oxygen species (ROS) detoxifying enzymes such as GPx, SOD, glucose-6-phosphate, GST, and CAT, which were significantly ($P < 0.001$) attenuated by UFG in a dose-dependent treatment. The UFG-PLGA-NP treatment confirmed the marked alteration in the content of detoxifying enzymes. The results confirmed that the UFG-PLGA-NP significantly ($P < 0.001$) modulated the DEN-induced alteration in the content of nonenzymatic antioxidant parameters (Figure S8).

Effect of UFG-PLGA-NP on inflammatory mediators

Figure 4 represents the proinflammatory cytokines such as TNF- α , IL-6, and IL-1 β . The increased level of TNF- α in diseased rats was significantly ($P < 0.001$) reduced by UFG-PLGA-NP at the end of the experimental study. Proinflammatory cytokines, namely, IL-6, displayed a similar trend as that of TNF- α . DEN group rats showed the enhanced level of IL-6 as compared to normal group rats. Rats in the UFG-PLGA-NP-treated group showed the significant ($P < 0.001$) decline in IL-6 level. DEN-induced rats showed the increased level of IL-1 β as compared to normal control, which was significantly ($P < 0.001$) restored by UFG-PLGA-NP.

Effect of UFG-PLGA-NP on the histopathology

Histopathological changes of normal, and DEN- and UFG-PLGA-NP-treated rats are well defined in Figure 5. Normal control group rats showed the normal, typical structure distinguished with normal architecture with small uniform nuclei,

Figure 4 Effect of UFG-PLGA-NP on proinflammatory cytokines in DEN-induced hepatocarcinogenesis rat.

Notes: Proinflammatory cytokines were assessed in terms of altered level of (A) TNF- α , (B) IL-6, and (C) IL-1 β as described in the "Materials and methods" section. DEN control group compared with normal control group. ### $P < 0.001$ is considered as extremely significant and the treated groups compared with the DEN control. * $P < 0.05$ is considered as significant and *** $P < 0.001$ is considered as extremely significant. Statistical analysis was performed by one-way analysis of variance followed by the Dunnett's test.

Figure 5 Effect of UFG-PLGA-NP on normal control and DEN-induced hepatocarcinogenesis rats histopathology.

Notes: (A) Normal control: rats showed the normal histopathology, (B) DEN control: showed the inflammatory blood vessels, macrodroplet of fats, cell swelling, cytoplasm with dark and irregular shaped, pseudoacini, hyperchromatic nuclei, necrosis, and disorganized hepatic parenchyma with thick cords and irregular polyhedral cells with bordering wide sinusoids, (C) DEN + UFG (5 mg/kg): showed the inflammatory blood cells, necrosis, irregular architecture, less altered hepatocytes, less enlarged karyomegali, proliferation in portal area of HSCs, and HSCs' focal proliferation with less macrodroplets of fats, (D) DEN + UFG (50 mg/kg): treated rats showed the less inflammatory blood vessels, cell necrosis, and less macrodroplet of fats accumulated in the rat liver, (E) DEN + UFG-PLGA-NP-treated rats showed no necrosis in the cell and blood vessels, less inflammatory blood vessels, and compact cytoplasm with normal size of karyomegali and bile duct. Original magnification 10 \times ; DXIT 1200, Nikon, Japan.

Abbreviations: DEN, diethyl nitrosamine; HSCs, hepatic stellate cells; PLGA, poly(d,l-lactide-co-glycolide); UFG, umbelliferone β -D-galactopyranoside; UFG-PLGA-NP, UFG-loaded PLGA nanoparticles.

average central vein, small uniform nuclei of cytoplasm, and normal polyhedral-shape hepatocytes (Figure 5). Cell necrosis with inflammatory blood vessels, nonsystemic hepatic parenchyma with thick cords (trabeculae), small dark cytoplasm with irregular structure, hyperchromatic nuclei, and pseudo acini was observed in DEN rats, and the observed feature confirmed the hepatic toxicity. Hepatic portion of DEN-treated rats confirmed the expansion of proliferation in the portal area of hepatic stellate cells (HSCs) and induces the focal proliferation in HSCs. Abnormal hepatocytes, which contain the irregular macro lipid droplets, binucleate, and masses of eosinophils in vacuolation surrounded by the cytoplasm, are also observed in histopathological slides. DEN rats treated with UFG confirmed the improvement in histopathological changes including less inflammatory necrosis cells, superior hepatocellular architecture, less altered hepatocytes, less or complete absence of the proliferation in the portal area of HSCs, and few microdroplets observed as compared to DEN control histopathology. The effect of UFG on the histopathological changes was dose dependent. The UFG-PLGA-NP-treated rats exhibited less inflammatory cells without microdroplets, and also contained compact cytoplasm, with an average-sized mononucleus (Figure 5).

Discussion

The current protocol was an attempt to formulate the polymeric nanoparticles with an effort to curb the expansion of hepatocarcinogenesis in Wistar rats by oral feeding of UFG-loaded polymeric nanoparticles. UFG-PLGA-NP stages higher concentration of UFG in the liver and is highly efficient in thwarting the DEN-induced HCC. The nanoparticles formulated from PLGA have sustained drug release capability and are biodegradable, nontoxic, and nonimmunogenic in nature. The two factors size and size distribution of nanoparticles take important part in the determination of stability, drug release, and cellular uptake efficiency.²² The smaller size of particle provides the greater window to release the drug into the systemic circulation via reticuloendothelial system. Cancer cells have the capability to concentrate a drug 20 times more when distributed via nanoparticulate preparation, and the underlying reason is the retention effect and increased permeability of such compounds.^{18,19}

HCC initiated by DEN, in rodent, is one of the most accepted experimental models for liver cancer, which allows the selection of the probable anticancer compounds on different phases of neoplastic transformation and expansion.²⁰ Here, we have scrutinized the chemoprotective effect of nanoformulation of UFG on DEN-induced hepatocarcinogenesis

in rats and tried to decipher the possible mechanism of action. During the study, we observed the development of the hepatic nodules in the DEN-induced rats, which were comparatively lesser in UFG-treated rats, in a dose-dependent manner. DEN-induced rats confirmed the expansion of hepatocyte nodules with the size (3 mm).²⁴ The hepatocytes that have been recognized for preneoplastic nodules for prominent hyperplasia, amendment in genes for cell proliferation, and enzymatic markers are well documented to establish the relation. Several researchers have confirmed that the development of hepatocyte nodules plays an important role as a precursor of HCC.^{19,20} During the course of study, the result illustrated that the nanoformulation of UFG suppressed the development of hepatic nodules and decreased the content of hepatic serum enzymes in experimental rats.^{21,22} The result accomplished the objective of our hypothesis by decreasing the development of hepatocyte nodules and restoring the hepatic enzyme against DEN intoxication.²³ We also found that the UFG nanoformulation was relatively efficient against eliminating the hepatic toxicity induced by DEN.

AFP, considered as the gold standard marker, was used in the estimation of HCC along with other serum parameters. The shape, size, and composition of the AFP are similar to the albumin, but the estimation process of AFP is rapid as compared to other albumins. AFP is generally used for the estimation of hepatocarcinoma and also for evaluating tumor growth.²⁴ The results of DEN-induced HCC group exhibited increased level of AFP, 10 times more than the normal control rats, which was significantly ($P < 0.001$) reduced by UFG nanoformulation in a dose-dependent manner. Further, our results established the preventive effect of UFG in UFG-NP-treated rats as compared to DEN control rats, by decreasing hepatic nodules, as evident from the microscopic and histopathological evaluation of each group (Figure 4).¹⁷

The ALP, ALT, and AST are the hepatic markers to judge the condition of liver. These transaminase enzymes are mostly present in heart, liver, and muscle. Any injury or damage of tissue or organ leads to oozing of these enzymes in circulating blood along with other enzyme and intercellular proteins. Determination of the serum ALT and AST levels advises the normal or altered function of liver.^{25,26} Functional integrity and cellular injury of the liver cell membrane can easily be scrutinized if there is enhanced content of AST and ALT in serum. DEN control group rats showed the increased level of AST and ALT and confirmed the hepatic toxicity.^{23,24} DEN-induced rats treated with nanoformulation of UFG significantly ($P < 0.001$) decreased the content of AST and ALT in a dose-dependent manner. The hepatoprotective nature of

drug/isolated compound can be appraised by its potential to restore or protect the liver functional mechanism that was induced by DEN carcinogenesis.

Hematological parameters used to identify the interaction between the biological system and chemicals in vivo system suggest the systemic effects. RBC play an important role during the respiration; they contain Hb, which transports the oxygen to the tissue and revert the carbon dioxide to the lungs. The reduced level of RBC and Hb indicates anemia. Another hematological parameter, WBC, defends the body against the infections. The DEN-induced HCC showed the increase in the level of WBC and suggests the enhancement of the pathological condition and immunological activity.³²

Oxidative stress induced by generation of reactive nitrogen species/ROS and free radicals including peroxy-nitrite, superoxide, hydrogen peroxide, and hydroxyl radical is a result of injury or due to decreased content of antioxidant or inflammatory reaction via nuclear factor-kappa B (NF- κ B).^{18,27} During hepatic carcinogenesis, the generation of free radicals and their reaction with lipid to produce LPO is considered as the important mechanism for corpuscle damage. The initiation of LPO starts the production of toxic radicals such as MDA, hydrogen peroxide, F2-isoprostanes, hydroxyl radicals, and 4-hydroxynonenal, which causes cell death, cell membrane damage, cellular function, oxidative stress, and carcinogenesis.^{35,36} The content of MDA and CD was increased during the HCC development from increased production of free radicals such as alkoxy and peroxy radicals, and enhanced the deposition of these radicals to cause the tissue toxicity and dysfunction of endogenous antioxidant systems. The results revealed that increased level of CD and MDA in DEN control group was significantly declined by the nanoformulation of UFG. The possible mechanism of action of UFG may be inhibition of alkoxy and peroxy radical production resulting in hepatoprotective effect in hepatic cancer. SOD and CAT are considered as the first-line antioxidant enzymes; SOD scavenges the superoxide to hydrogen peroxide and CAT scavenges and detoxifies the hydrogen peroxide. The restoration of these enzymes is also attributed to our formulation.²⁴⁻²⁸ Histological studies reveal that the HCC expansion occurs in the backdrop of chronic inflammation and NF- κ B is the chief mediator of inflammation, regulating other inflammatory molecules either downstream or upstream.^{18,23,29} Liver is the production center for synthesis of cytokines such as TNF- α , IL-1 β , and IL-6 by blood cells (monocytes and lymphocytes). Not only liver but also few other cells such as murine, kupffer cells, and human hepatocytes produce IL-1 β , IL-6, and TNF- α .

Cytokines such as IL-6, secreted from the kupffer cells via modulating the NF- κ B signaling, are MyD88 dependent, which further activate the IL-1 α from hepatocytes.^{37,38} Other cytokines such as TNF- α (NF- κ B activator) have a significant role in the inflammatory reaction and also play a critical role in the cell proliferation. The possible underlying mechanism to initiate hepatocarcinogenesis by DEN may be from its effects on kupffer cells via activation of NF- κ B, which regulates the inflammatory mediators such as IL-6 and TNF- α into the circulation.^{30,31} It also plays a dual role in the development of neoplasia, induction of necrosis, and expansion of fibroblasts and other tumor cells, and also has secondary role in demolishing the cancer vasculature. Experimental evidence suggested that TNF- α accelerates the production of genotoxic molecules and induces the antiapoptotic molecules that are NF- κ B dependent, which confirm its effect on tumor growth.³⁰⁻³⁴ DEN group rats treated with UFG-PLGA-NP showed the decrease in the level of TNF- α as compared to DEN control. The possible mechanism of action of UFG-PLGA-NP may be by inhibiting the production of genotoxic molecules as well as reducing the antiapoptotic molecules that are NF- κ B dependent. In relation to cancer progress, UFG may be a beneficial chemopreventive tool but the complexity remains to determine the efficient dose and time of administration, and to maneuver the compound to the target site needs some more in-depth study.
