**Purpose:** The nociceptin receptor (NOP) was discovered in 1994 and was designated opioid-like receptor; activation of NOP leads to reduced neuronal excitability. Although suggested by the anatomical localization of NOP in brain or spinal cord, the cardiovascular or nociceptive effects of its endogenous ligand, nociceptin, are equivocal. Taking advantage from intrathecal application of nociceptin to simultaneously activate NOP on sympathetic preganglionic neurons in the intermediolateral column (IML) and superficial laminae of dorsal horn, we investigated whether the nociceptin-induced cardiovascular effects engage the participation of baroreflex, and whether the concurrently elicited changes in blood pressure and pain responses are interrelated.

**Methods:** NOPs in the thoracic spinal cord of ICR or C57BL/6 mice were identified with immunofluorescence staining and were activated through intrathecal administration of nociceptin. The elicited changes in cardiovascular parameters and tail-flick nociceptive responses were measured.

**Results:** Positive immunoreactivity against NOP colocalized with neurons in the IML and superficial dorsal horn layers of thoracic spinal cord. Intrathecal administration of nociceptin (1, 2, or 5 nmol) elicited a significant and dose-dependent decrease in blood pressure or heart rate that was paralleled by reduced baroreflex-mediated sympathetic vasomotor tone and mirrored by augmented cardiac vagal baroreflex, alongside prolonged tail-flick latency with an efficacy of hypotension <<< antinociception. Coadministration of the specific NOP antagonist, UFP101 (10 nmol), blunted all nociceptin-elicited responses. However, restoring blood pressure to baseline level failed to affect the antinociceptive actions of nociceptin.

**Conclusion:** Activation of thoracic spinal NOP in ICR and C57BL/6 mice induces blood pressure and heart rate by decreasing the sympathetic outflow of both arms of the baroreflex arc to the blood vessels and the heart, and the antinociceptive responses to nociceptin are independent of and disproportional to its cardiovascular actions.

## Introduction

The nociceptin receptor (NOP) was discovered in 1994 and was designated opioid-like receptor (ORL-1) because it shares a high homology of amino acid sequence with opioid receptors although its affinities for opioid ligands are greatly reduced.<sup>1</sup> The highly selective and endogenous ligand for NOP, which was discovered in 1995, is the 17-amino acid neuropeptide nociceptin/orphanin FQ.<sup>2</sup> Nociceptin shows only very modest affinity for  $\mu$ ,  $\delta$ , or  $\kappa$  receptors,<sup>3</sup> and naloxone does not antagonize most

of the effects of nociceptin.<sup>1</sup> At the cellular level, activation of NOP by nociceptin inhibits the formation of cyclic adenosine monophosphate, mediates a pronounced inhibition of voltage-gated  $\text{Ca}^{2+}$  channels, and facilitates the opening of inwardly rectifying  $\text{K}^{+}$  channels.<sup>4–6</sup> The overall effect of NOP activation leads to reduced neuronal excitability and reduction of neurotransmitter release.<sup>7,8</sup>

Anatomical studies have shown that NOP is localized in brain or spinal nuclei that are related to cardiovascular or nociceptive responses.<sup>9–11</sup> However, nociceptin has been reported to decrease or increase blood pressure (BP) or heart rate (HR).<sup>7,12–15</sup> Likewise, nociceptin reportedly produces hyperalgesia and allodynia,<sup>2,3,16</sup> or antinociception.<sup>16,17</sup> These equivocal cardiovascular and antinociceptive effects of nociceptin may have arisen from differences in sites of action because of the routes through which this peptide was administered. In particular, the disparate cardiovascular responses to nociceptin may have resulted from differential effects induced by this peptide on the baroreflex-mediated sympathetic vasomotor tone and cardiac vagal baroreflex, which are responsible, respectively, for the short-term and long-term regulation of BP and HR.<sup>18,19</sup> Another possibility arises from the complex relationship between BP and pain. Whereas hypertension has generally been associated with hypoalgesia,<sup>20,21</sup> increased pain sensitivity in chronically low BP or hypotension concomitant with antinociception has also been reported.<sup>22–24</sup>

Intrathecal application of nociceptin simultaneously acts on NOP present in the dorsal horn where primary afferents from nociceptive receptors terminate,<sup>25</sup> and intermediolateral (IML) column where sympathetic preganglionic neurons that innervate the blood vessels and the heart reside.<sup>26</sup> The present study exploited this advantage to decipher whether by acting on the IML, which constitutes the common sympathetic output component in the circuit for the baroreflex-mediated sympathetic vasomotor tone and cardiac vagal baroreflex, the cardiovascular effects of activation of NOPs in the spinal cord engage the participation of both arms of baroreflex. We also examined whether, on an equimolar basis, the concurrently induced changes in BP and pain responses by nociceptin are interrelated.

## Materials and methods

### Ethics statement

All experimental procedures carried out in this study were approved by the Institutional Animal Care and Use Committee of the Kaohsiung Chang Gung Memorial Hospital and were in compliance with the guidelines for animal care and

use set forth by that committee. All efforts were made to reduce the number of animals used and to minimize animal suffering during the experiment.

### Animals

Adult male ICR mice (30–35 g,  $n=33$ ) or C57BL/6 mice (28–30 g;  $n=62$ ) were purchased from the Experimental Animal Center of the Ministry of Science and Technology and BioLASCO, Taiwan, Republic of China. They were housed in an AAALAC International-accredited Center for Laboratory Animals under temperature control ( $24^{\circ}\text{C}$ – $25^{\circ}\text{C}$ ) and 12 hour light–dark cycle. Standard laboratory mouse chow and tap water were available ad libitum.

### Double immunofluorescence staining

We examined the expression of NOP in the dorsal horn and IML of the thoracic spinal cord by double immunofluorescence staining.<sup>27</sup> Mice that received an intraperitoneal injection of pentobarbital sodium ( $50\text{ mg kg}^{-1}$ ) were transcardially perfused with warm isotonic saline solution, followed by ice-cold 4% paraformaldehyde in 0.1 M PBS (pH 7.2). The thoracic spinal cord was removed, postfixed by submersion in the latter solution overnight at  $4^{\circ}\text{C}$ , and cryoprotected by 30% sucrose in 0.1 M PBS. Frozen transverse section ( $20\text{ }\mu\text{m}$ ) of the thoracic spinal cord was cut on a cryostat (Leitz, Wetzlar, Germany) and collected in 0.1 M PBS. The staining procedures were modified from those reported previously.<sup>27</sup> In brief, free-floating sections of the thoracic spinal cord were incubated with a rabbit polyclonal anti-NOP antiserum (orb11143; Biorbyt, Cambridge, UK), together with a mouse monoclonal anti-NeuN antiserum (MAB377, Chemicon, Temecula, CA, USA). The sections were subsequently incubated concurrently with two appropriate secondary antisera (Molecular Probes, Eugene, OR, USA), a goat anti-rabbit IgG conjugated with Alex Fluor 488 (A11034) for NOP, and a goat anti-mouse IgG conjugated with Alexa Fluor 586 (A11031) for NeuN. The specificity of NOP antiserum was validated by its omission from the staining procedure. Viewed under a Fluoview FV1000 laser scanning confocal microscope (Olympus, Tokyo, Japan), immunoreactivity for NeuN exhibited red fluorescence, and NOP exhibited green fluorescence.

### Subarachnoid catheterization

The design and implantation of thoracic intrathecal catheters in mice followed our previously developed procedure.<sup>28</sup> Briefly, under pentobarbital sodium anesthesia ( $50\text{ mg kg}^{-1}$ , intraperitoneal), the left interspinous space between T12 and

T13 was exposed after the supraspinous ligament and the left interspinous ligament between T12 and T13 was removed. A 0.5 cm long PU-10 catheter (Strategic Application Inc., Libertyville, IL, USA) was inserted tangentially into the subarachnoid space along the dorsal surface of the spinal cord through a dural opening. After flushing with 3–5  $\mu$ L of artificial cerebrospinal fluid (aCSF), the exterior end of the catheter was sealed by heat. The catheter was further secured on the fascia of the paravertebral muscle with suture, and the sealed end was buried under the skin. Sodium penicillin (1,000 IU) was given intramuscularly to prevent postoperative infection. The animals were returned to the animal room (temperature maintained at  $24^{\circ}\text{C} \pm 0.5^{\circ}\text{C}$ ) for postoperative recovery. They were allowed free access to standard mouse chow and water. Only animals that showed full recovery 4–5 days after surgery and with no observable motor deficit were used in subsequent experiments.

## General preparation for physiologic experiments

Anesthesia was induced in an induction chamber with 4% isoflurane (Abbot Laboratories, Abbot Park, IL, USA) in oxygen for 30 seconds at a constant flow of 1.0 L/min using a Matrx VIP 3000 vaporizer (Midmark, Orchard Park, NY, USA).<sup>29</sup> After induction, mice were placed on an operating table and anesthesia was maintained with 2% isoflurane in 100% oxygen through a nose piece to carry out preparatory surgery. This included cannulation of the right femoral artery with a PE-10 catheter (Clay Adams, Franklin Lakes, NJ, USA) to measure arterial pressure. In some experiments, the left femoral vein was also cannulated with a PE-10 catheter (Clay Adams). After surgery, animals were placed on a mouse adaptor (Kopf, Tujunga, CA, USA) and were connected to the anesthesia machine (Univentor, Zejtun, Malta) with a mouse mask (Kopf).

## Determination of BP, HR, and spontaneous baroreflex

Anesthesia was maintained at 1% isoflurane during the recording session, and mice were placed on a heating pad and their rectal temperature was maintained at  $37^{\circ}\text{C} \pm 0.5^{\circ}\text{C}$ . The recorded BP signals from the femoral artery were processed by an arterial BP analyzer (Notocord, Croissy-Sur-Seine, France) and the systolic blood pressure (SBP) signals were simultaneously subject to online and real-time spectral analysis (Notocord) to detect the power density of the low-frequency component of SBP spectrum (BLF; 0.15–0.6 Hz).<sup>30,31</sup> The power density of this spectral

band has been demonstrated to be a valid experimental index for spontaneous baroreflex-mediated sympathetic vasomotor tone.<sup>30–33</sup> To evaluate the spontaneous cardiac vagal baroreflex, we employed a baroreflex sequence analyzer (Notocord) to determine baroreflex sensitivity (BRS) based on online detection of spontaneous sequences of consecutive increases or decreases in SBP associated with parallel changes in HR.<sup>31,34</sup> With reference to Laude et al,<sup>33</sup> the settings were analysis window: 60 seconds; synchronization delay: three cycles; and minimum sequence length: three cycles. HR was derived instantaneously from the BP signals. Concurrent temporal changes in SBP, mean arterial pressure (MAP), and HR were continuously recorded, alongside power density of the BLF band or BRS. To avoid potential bias created by nonstationary disturbances, only stationary segments of data from spectral analysis were used for statistical analysis.

## Tail-flick nociceptive test

We employed the tail-flick nociceptive test because this paradigm evaluates specifically spinally-mediated pain responses.<sup>35,36</sup> Under concurrent measurement of the cardiovascular responses as described earlier, the tail of the mice was immersed in a hot water bath maintained at  $55^{\circ}\text{C} \pm 0.5^{\circ}\text{C}$ . The time taken for the animal to flick its tail away from hot water was recorded, with a cutoff time of 15 seconds imposed to prevent tissue damage. The averaged value of three determinations separated by 1 minute was taken as the measured tail-flick response.

## Intrathecal administration of nociceptin and its antagonist

The sealed end of the implanted subarachnoid catheter was retrieved and was flushed with 3  $\mu$ L of aCSF to ensure patency. Nociceptin,<sup>37</sup> a selective agonist of NOP (1, 2, 5 nmol; Tocris Bioscience, Bristol, UK), was given at a volume of 3  $\mu$ L over 1 minute using a 25  $\mu$ L Hamilton microsyringe, followed by an additional 3  $\mu$ L of aCSF to flush the catheter. In experiments that engaged the specific antagonist,<sup>36</sup> UFP101 (10 nmol; Tocris Bioscience) was similarly delivered intrathecally, together with nociceptin (5 nmol) or aCSF. The doses used were adopted from the relevant literature.<sup>36,37</sup> The effects of drug treatments on MAP, HR, BLF power, and BRS were routinely followed for 60 minutes after administration, and the effects on tail-flick responses were evaluated 30 minutes after intrathecal injection of nociceptin or UFP101 plus nociceptin. Injection of 3  $\mu$ L of aCSF served as the vehicle control for nociceptin and UFP101.

## Evaluation of relationship between tail-flick responses and BP

In some experiments, after the effects of intrathecal administration of nociceptin on tail-flick responses as described in the tail-flick nociceptive test earlier were completed, the BP was titrated back to baseline level by intravenous infusion of dopamine. Tail-flick latency measurements after nociceptin administration were repeated after stabilization of the cardiovascular parameters.

## Statistical analysis

Data were expressed as mean  $\pm$  SEM. They were analyzed using one-way ANOVA or two-way ANOVA with repeated measures for assessment of group means, followed by the Scheffé or Dunnett post hoc multiple-range analysis for individual means. Statistical significance was accepted at  $P < 0.05$ .

## Results

### NOP is present in the dorsal horn neurons and IML column of thoracic spinal cord

Based on the anatomical location of immunoreactivity in the spinal cord (Figure 1A), double-immunofluorescence staining revealed that NOPs were distributed in the dorsal horn and IML column of the thoracic spinal cord (Figure 1B). Viewed under a laser scanning confocal microscope, NOP immunoreactivity was found to intermingle with cells stained positively with the neuronal marker, NeuN, in the superficial layers of the dorsal horn (Figure 1C–E), or colocalized with NeuN-positive cells in the IML (Figure 1F–H) of the thoracic spinal cord.

### Activation of spinal NOP decreases BP, HR, or baroreflex-mediated sympathetic vasomotor tone and increases cardiac vagal baroreflex in ICR and C57BL/6 mice

Intrathecal administration of nociceptin (1, 2, or 5 nmol) in ICR mice elicited a significant and dose-dependent decrease in MAP and HR over our 60 minute observation period (Figure 2). The power density of the low-frequency (BLF) component of SBP spectrum, an experimental index for spontaneous baroreflex-mediated sympathetic vasomotor tone,<sup>30–33</sup> also underwent a dose-dependent reduction over a time course that paralleled the changes in MAP. At the same time, the BRS, an experimental index for spontaneous cardiac vagal baroreflex,<sup>31,34</sup> exhibited a dose-dependent increase that mirrored the decrease in HR. On the other hand, intrathecal administration of aCSF (vehicle control) was ineffective.

Repeating this series of experiments in C57BL/6 mice to exclude strain-related responses revealed comparable

results.<sup>38,39</sup> Intrathecal administration of nociceptin (1, 2, or 5 nmol) similarly resulted in a dose-dependent reduction in MAP, HR, or BLF power and augmentation in BRS over our 60 minute observation period (Figure 3). The only difference is that the nociceptin-elicited cardiovascular responses were shorter in duration in the C57BL/6 mice. Intrathecal administration of a specific NOP antagonist, UFP101 (10 nmol), when delivered together with nociceptin (5 nmol), significantly antagonized the decrease in MAP or BLF power and increase in BRS induced by this peptide (Figure 4).

### Activation of spinal NOP induces cardiovascular depression and antinociception in an independent and disproportional manner

In addition to the elicited cardiovascular responses, intrathecal administration of the three doses (1, 2, or 5 nmol) of nociceptin also simultaneously elicited a dose-dependent increase in tail-flick latency (Figure 5A), an experimental paradigm that evaluates specifically spinally mediated pain responses.<sup>35,36</sup> This antinociceptive effect was antagonized by coadministration of UFP101 (Figure 5B). On the other hand, the dose-dependent depression of tail-flick nociceptive responses was not affected (Figure 5A) on deliberately restoring the nociceptin-suppressed MAP, HR, or BLF power and enhanced BRS to baseline level by intravenous infusion of dopamine ( $0.8 \mu\text{g } \mu\text{L}^{-1}$ ) at an infusion rate of  $0.5 \mu\text{L min}^{-1}$  (Table 1). Of note is that, measured on an equimolar basis, the maximal increase from baseline in tail-flick latency (1 nmol, 126%; 2 nmol, 207%; 5 nmol, 536%) induced by nociceptin was discernibly larger than the maximal decrease from baseline in MAP (1 nmol, 6%; 2 nmol, 13%; 5 nmol, 21%).

## Discussion

The present study took advantage that intrathecal application of nociceptin simultaneously acts on NOP in the IML and dorsal horn to decipher whether this endogenous opioid peptide elicits its cardiovascular depressive effects by acting on the baroreflex-mediated sympathetic vasomotor tone and cardiac vagal baroreflex, and whether the concurrently induced changes in BP and pain responses are interrelated. Our results showed that activation of spinal NOP reduces BP and HR by decreasing the sympathetic outflow of both arms of the baroreflex arc to the blood vessels and the heart, and the antinociceptive responses to nociceptin are independent of and disproportional to its cardiovascular actions.

The baroreflex-mediated sympathetic vasomotor tone and cardiac vagal baroreflex represent the most fundamental

regulatory mechanisms for short-term and long-term maintenance of BP and HR.<sup>18,19</sup> To sustain a reduction in BP and HR, it is, therefore, imperative that the baroreflex-mediated sympathetic vasomotor tone must be depressed and the cardiac vagal baroreflex augmented. Our present results revealed that this essential modus operandi indeed underlies the cardiovascular depressive effects of activation of spinal NOP.

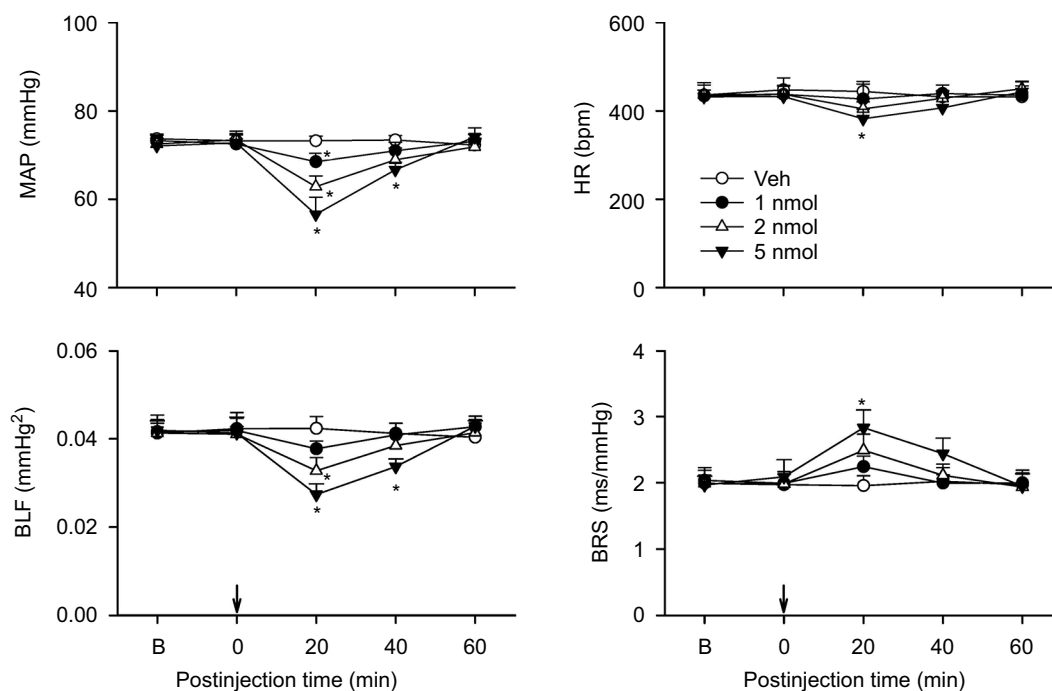

We found that on intrathecal administration of nociceptin, the decrease in BLF power and increase in BRS, our experimental indices for the two arms of the baroreflex, were accompanied by concomitant reduction in MAP and HR. Lai et al<sup>8</sup> showed in rat slices that nociceptin concentration-dependently suppresses the excitatory postsynaptic potentials evoked by focal stimulation and hyperpolarizes a population of antidromically

identified sympathetic preganglionic neurons. It is, therefore, conceivable that activation of NOP on the IML neurons sustains a decrease in BP by lessening the efficacy of the baroreflex-mediated sympathetic vasomotor tone via a reduction in sympathetic outflow to the blood vessels. On the other

hand, by inhibiting the IML neurons, nociceptin sustains a decrease in HR by potentiating the cardiac vagal baroreflex via a reduction in sympathetic excitatory outflow to the heart that normally balances the cardiac inhibitory effects of the vagal outflow from the nucleus ambiguus.

Direct injection of nociceptin into the nucleus tractus solitarius increases BP and HR,<sup>15</sup> and microinjection of this peptide into the rostral ventrolateral medulla causes hypotension and bradycardia.<sup>14</sup> Electrophysiologic results from rat slices also showed that nociceptin decreases GABAergic neurotransmission to cardiac vagal neurons in the nucleus ambiguus.<sup>40</sup> Collectively, these observations are consistent with the notion that nociceptin may act on key components of the baroreflex circuits to depress baroreflex-mediated sympathetic vasomotor tone and enhance cardiac vagal baroreflex. It is, therefore, possible that our present results may have arisen

from inadvertent diffusion of the intrathecally delivered nociceptin to the brain stem. This possibility is deemed unlikely because we have demonstrated that given intrathecally at a volume of 3 µL using our method, the highest levels of the spinal cord that the injected agents may reach are T1–T2.<sup>28</sup>

The relationship between BP and pain is equivocal at best. Hypoalgesia has been described in animal models of hypertension.<sup>20,41,42</sup> An inverse relationship between BP and pain sensitivity has also been reported.<sup>23</sup> Based on concurrent evaluation of changes in BP and pain responses, our results revealed that the cardiovascular actions of spinally-applied nociceptin are independent of and disproportional to its antinociceptive effects. We demonstrated that restoring the reduced MAP, HR, or BLF power and augmented BRS to baseline levels with the infusion of dopamine did not affect the increase in tail-flick latency induced by nociceptin. Intriguingly, for a given dose, there was a disproportional degree of inhibition in the order of antinociception >>> hypotension. Similar observations have been reported previously for clonidine and guanabenz.<sup>22,24</sup> Nevertheless, our study design does not allow us to offer a mechanistic explanation. Speculatively, on an equimolar basis, the much larger areas and hence presumably higher presence of NOP in the dorsal horn when compared to the IML may account for the differential cardiovascular depressive and antinociceptive effects of nociceptin. Nociceptin has been shown to produce biphasic effects in the hole-board exploration test in mice.<sup>43</sup> Perhaps its depressive effects on nociception and cardiovascular function are similarly manifested. By showing that nociceptin induced dose-dependent cardiovascular depression and antinociception (Figures 2, 3, and 5A), the possibility for nociceptin to exhibit biphasic dose-related responses is deemed minimal.

Denayer et al<sup>44</sup> pointed to the importance of selecting the appropriate mouse strain for mechanistic investigation. Mattson<sup>38</sup> and Mogil et al<sup>39</sup> also drew attention to potentially strain-related differences in cardiovascular and antinociceptive responses. By showing comparable results from an outbred strain (ICR mice) and inbred strain (C57BL/6 mice), we confirmed that our observed cardiovascular responses to nociceptin were not strain-specific. We recognize that our results on tail-flick latency were obtained under 1% isoflurane and may hence be confounded by the use of anesthesia. However, as our experimental design calls for simultaneous evaluation of the cardiovascular responses, an appropriate level of sedation is a mandatory requirement by our Institutional Animal Care and Use Committee. We reason that as the tail-flick latency is a specific measurement of spinally mediated pain response,<sup>35,36</sup> and intrathecal administration of nociceptin elicited a dose-related increase in this nociceptive

response that is independent of its cardiovascular effects, the influence of anesthesia on our results is deemed minimal. The doses of nociceptin we used (1, 2, or 5 nmol=1.8, 3.6, or 9 µg) in anesthetized mice compared favorably with the intrathecal antinociceptive half-maximal effective dose value (8.2 µg) in awake mice.<sup>45</sup>

## Conclusion

Based on the concurrent activation of NOP on the IML and dorsal horn via the intrathecal route, the present study revealed that nociceptin reduces BP and HR by decreasing the sympathetic outflow of both arms of the baroreflex arc from the IML to the blood vessels and the heart. We further found that the cardiovascular depressive actions of nociceptin are independent of its antinociceptive responses and were in the order of hypotension <<< antinociception. The latter finding may have promising therapeutic implications, because it is ideal to have a drug that is high in antinociceptive potency and has much lower depressive effects on hemodynamic functions.

## Acknowledgments

This work was supported in part by research grants from the Chang Gung Medical Foundation CMRPG8A0851 (to Y.Y. Poon) and OMRPG8C0021 (to S.H.H. Chan). The funding body plays no role in the design of the study, data collection, analysis, interpretation of the data, or in writing the manuscript. The abstract of this paper was presented at the 18th World Congress of Basic and Clinical Pharmacology held at Kyoto/Japan, July 1–6, 2018, as a poster with interim findings. The abstract is available online at [https://www.micenavi.jp/wcp2018/search/detail\\_program/id:1816](https://www.micenavi.jp/wcp2018/search/detail_program/id:1816).

## Journal of Pain Research

### Publish your work in this journal

The Journal of Pain Research is an international, peer reviewed, open access, online journal that welcomes laboratory and clinical findings in the fields of pain research and the prevention and management of pain. Original research, reviews, symposium reports, hypothesis formation and commentaries are all considered for publication.

Submit your manuscript here: <https://www.dovepress.com/journal-of-pain-research-journal>

Dovepress

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
