Background: Pancreatic cancer is a malignant disease with a high mortality rate and severe pain that is challenging to manage. To reduce the excruciating abdominal pain, opioids and adjuvant agents are conventionally used.

Objectives: PRNCPB is a treatment of neural therapy. The number of studies assessing the effect on patients' QoL is limited and inconsistent. With this study, we intended to address this issue.

Study design: A prospective nonrandomized study with a series of cases of unresectable pancreatic cancer was conducted.

Setting: The study was performed at our pain clinic under real life conditions.

Materials and methods: A total number of 16 patients with severe abdominal pain were enrolled in the study all of whom had responded to combined systemic analgesic therapy inadequately and had intolerable side effects contraindicating further increase in dose. The efficacy of this invasive, palliative analgesic procedure was evaluated 35 days after PRNCPB was performed. Primary outcomes were changed in pain intensity using the VAS questionnaire. Secondary outcomes were improved in QoL using the SF-36 questionnaire. Changes in pain medications and adverse reactions were monitored.

Results: After PRNCPB patients experienced a significant decrease ($P=0.002$) in pain intensity as shown by the VAS score, and a decreased opiate demand. Their QoL scores considering effect sizes also improved ($P<0.001$). No complications attributable to PRNCPB were observed during the study period. Additionally, no adverse drug reactions were observed.

Limitations: Detection, observation, and reporting bias can be estimated as moderate. Selection bias was not detected.

Conclusion: Our results give preliminary evidence that PRNCPB might be helpful as an additional treatment to conventional pain management in end-stage pancreatic cancer patients. PRNCPB seems to improve QoL in these patients in a time frame of at least 5 weeks after intervention.

Keywords: pancreatic cancer, cancer pain, celiac plexus, neural therapy, plexus block, palliative care, quality of life

Introduction

Pancreatic cancer is becoming more common worldwide; in Western countries, the disease ranks fourth to fifth in the list of cancers leading to death. It is more common in men than in women (male to female ratio 2:1), most prevalent in patients aged 55–75 years, in smokers, and those who regularly consume large amounts of alcohol. Other etiologic factors include aggregation in families, heredity, and obesity.^{1–3} Long-term survival is exceedingly low, such that the incidence of the disease is practically identical with its mortality.^{1,3–5}

The first symptoms usually are weight loss, epigastric, or upper abdominal pain associated with icterus, pruritus, and anorexia. At the time of diagnosis, 73% of patients already suffer from abdominal pain.^{6,7} Few options are available to treat the severe pain typically present in advanced pancreatic cancer.

Pathogenesis of tumor pain

Pain in pancreatic cancer is typically located in the epigastrium radiating band-like to the back. Its etiology appears to be complex, possibly involving blockage in the pancreatic duct, increased parenchymal pressure, and superimposed peritumoral edema. At the level of nociception, the most important mechanism – estimated at 70%–90% – is the neuropathic pain associated with the infiltration of the nerves by cancer cells and perineural invasion. The neural processing of the pain includes four stages: transduction, transmission, modulation, and perception.^{8–10} The continuous impulse of permanent pain may result in the development of central pain syndrome.⁹

Management of tumor pain

The pain caused by pancreatic cancer is of multifactorial origin, so the strategy of pain management should also be multifactorial.^{10–14} A well-chosen effective pain relief can significantly improve the QoL of patients including end-stage cancer.^{15,16} The most widely accepted pain management strategy is the four-step “analgesic ladder” recommended by the WHO and IASP;^{17,18} it provides the most effective analgesia with relatively few side effects and complications.^{11,18,19} When conservative analgesia is no longer effective and the

dose of analgesic can no longer be increased due to patient intolerance, invasive methods to control pain become more and more appropriate.^{19–21}

Gastrointestinal, surgical, and oncological treatments and interventions aiming to maintain the patency of ducts and to reduce pancreas edema are necessary for adequate pain control.^{12,22,23} Despite these measures, severe pain often persists rendering the introduction of noninvasive and palliative methods unavoidable (Table 1).^{17,18,24,25}

In general, the preferred route of drug administration is enteral; however, transdermal application, rectal, subcutaneous, intramuscular, or intravenous drug administrations are also feasible. If the pain becomes intolerable after 5 days of therapy or if the intensity of pain reaches level 6 on the VAS before the fifth day, then the dose should be increased, the adjuvant drug should be replaced, or pain control should move a step higher.^{13,26,27}

Celiac plexus neurolysis

The most effective method of invasive pain management in pancreatic cancer is CPN.²⁸

In 1914, Kappis published his experience with the blockade of the splanchnic nerve and celiac plexus with a percutaneous technique.²⁹ Despite various technical modifications, this study still remains the “gold standard.”^{30,31} The local anesthetic block of the plexus is effective in the early stage of cancer, but only for a short period. The efficacy rate of neurolysis is ~80%, reducing pain for several weeks or months.³²

CPN may be performed during laparotomy or thoracoscopy or by various percutaneous techniques: anterior or

Table 1 Treatment of cancer-related pain

Pain intensity				
	1. Step	2. Step	3. Step	4. Step
VAS	1–3 mild pain	4–6 moderate pain	7–10 severe pain	7–10 severe pain
Medications	Nonopioid analgesics: paracetamol, NSAID-s, salicylate, selective COX-2 inhibitors	Drugs from first step + mild opioids: codeine, hydrocodeine, tramadol	Drugs from second step + strong opioids: morphine, hydromorphone, fentanyl, oxycodone, pethidine	Drugs from third step + neurolysis, nerve block, spinal cord stimulations, implanted opioid pumps, radiofrequency lesioning, cryotherapy
	Adjuvant medications (antidepressants, anticonvulsants, antispasmodics, corticosteroids, local anesthetics antiemetics)	Adjuvant medications (antidepressants, anticonvulsants, antispasmodics, corticosteroids, local anesthetics antiemetics)	Adjuvant medications (antidepressants, anticonvulsants, antispasmodics, corticosteroids, local anesthetics antiemetics)	Adjuvant medications (antidepressants, anticonvulsants, antispasmodics, corticosteroids, local anesthetics antiemetics)

posterior paraspinal approach, intradiscal, retrocrural and transcrural, single and bilateral needle placements; trans- and para-aortic techniques; radiofrequency thermocoagulation; and using local anesthetics or neurolytics (6%–10% phenol, 70%–90% ethyl alcohol).^{33–36} Various imaging techniques can be used to perform these interventions accurately, including fluoroscopy, ultrasonography, or computed tomography.^{25,37–39}

Objectives

The retrocrural technique of NCPB is known to minimize the incidence of complications.^{14,20,40} The number of publications using the retrocrural technique is limited.^{14,20,34,40–43} Thus, we aimed to evaluate the analgesic efficacy of retrocrural NCPB in patients with unresectable pancreatic cancer by monitoring changes in analgesic medication use, effective pain control, and therapy-related adverse reactions. Since the effect of NCPB on patient's QoL is considered controversial,^{44–50} with this study, we intended to address this issue.

Study design

This prospective nonrandomized study was performed at our pain clinic (Pándy Kálmán Hospital, Gyula, Hungary) under real life conditions following the principles of the Declaration of Helsinki. Patients with pancreatic cancer suffering from abdominal pain were included, if they fulfilled the study's inclusion criteria and provided signed informed consent. The approval by the local research ethics committee [Békés Megyei Központi Kórház Pándy Kálmán Tagkórháza, Intézeti Kutatásetikai Bizottság (IKEB)] was given under the registration number: 244/2016. Patients were recruited in the period 06/01/2015–02/28/2017.

Materials and methods

Selection of patients

Patients with pancreatic cancer who visited our pain clinic were enrolled in the study if they met the following inclusion criteria.

Inclusion criteria

- Diagnosis of unresectable pancreatic cancer;
- A high-dose, combination pain medication regimen had been used (opioids and NSAID) for the previous 2 weeks, or contraindication to increase dose was present due to adverse drug reactions;
- Pain intensity of 7 or more on VAS;
- Patient was capable of understanding the information provided and to give consent to the intervention.

Exclusion criteria

- Coagulation disorder or oral anticoagulant therapy.
- General contraindications to neural therapy.

Evaluation – outcomes

Primary outcomes

- Pain intensity was measured by a VAS before and 35 days after the intervention.

VAS is a simple method to assess pain intensity from 0 (no perceived pain) to 10 (maximum perceived pain). Although the value is subjective, comparison of the numeric data before and after treatment is a valid indicator of therapeutic efficacy.^{51–53}

- Throughout the study type, application form and dosage of analgesic medication taken by the patients were monitored.

Secondary outcomes

QoL was assessed using the SF-36 questionnaire.

SF-36 is a generic, coherent, and easily administered quality-of-life questionnaire adapted in Hungary and recognized internationally.^{53,54} The questionnaire was completed individually before and 35 days after treatment. The administration time of the survey is ~20 minutes, and the patient can generally fill it out with little or no intervention from an interviewer.

“After” treatment results were compared with “before” treatment results. Patients' answers were presented in eight dimensions on a scale of 0–100. The dimensions are vitality, physical functioning, bodily pain, general health perceptions, physical role functioning, emotional role functioning, social role functioning, and mental health. The higher the total value of the points of each dimension, the healthier the responder feels.^{55–57}

Side effects and complications

Side effects and complications were monitored.

Statistical evaluation

An “internal control” of the post-treatment status compared with the pretreatment status was performed. The degree of changes was documented and analyzed. Change in pain intensity was calculated by Wilcoxon's test. The need for drug use was compared by using Fisher's exact test. Changes before and after treatments, in each dimension of the SF-36 questionnaire, were performed by Wilcoxon's test. A Bonferroni–Holmes method was used with *P*-values obtained

in statistical tests mentioned above to decide which changes might be accepted as significant at $P < 0.05$ taking into account the effect of multiple testing. Effect sizes were also calculated in cases of pain intensity and SF-36 dimensions. Data were recorded and analyzed using the SYSTAT 10 program package, as with previous studies and according to the SF-36 manual.^{55–57}

Description of the PRNCPB therapy Perioperative preparations

Prior to the intervention, the condition of patients was assessed and optimized (eg, electrolyte and fluid balance, coagulation parameters) when necessary. The invasive intervention was performed in accordance with professional recommendations. Peripheral intravenous cannulation, C-arm X-ray with printer, and noniodinated contrast agent were used. Following the intervention, patients were observed in a surgical step down unit for 1 hour.

Procedure

Throughout the procedure, verbal communication was maintained with the patients. Heart rate, blood pressure, and O_2 saturation were monitored. Patients were placed on the operating table in a prone position. In all cases, retrocrural penetration was performed: a horizontal line was drawn through the midline of the L1 vertebral body to the inferior edge of the 12th rib, on both sides. A line was drawn to these from the processus spinosus of Th12, on both sides. The meeting point of the lines is the entry site which is located about 7.5 cm lateral to the midline, just beneath the 12th ribs. Twenty-two gauge, 13–15 cm styleted needles are inserted bilaterally through the anesthetized areas. The needle is inserted medially at 45 degrees from the midline, so as to “walk off” the lateral surface of the L1 vertebral body. From here, the left-side needle is gradually advanced 2–4 cm deep, until the pulsations emanating from the aorta are felt. The right-side needle is inserted in 2–3 cm deeper past contact with the L1 vertebral body. From the needle to the right is the inferior vena cava. Finally, the tip of the two needles must be at the anterolateral edges of the aorta. About 2–2 mL of contrast material is injected bilaterally, and its spread observed radiographically. Ideally, on the fluoroscopic anteroposterior view, contrast material is confined to the midline and concentrated near the Th12-L1 vertebral body. A smooth posterior contour can be observed on the lateral view, in front of the vertebral body. If no aspirates were seen coming through the inserted needles and both needles were properly positioned, 5 mL of 1% lidocaine was injected per

side. If this did not lead to deterioration or spinal block, the neurolysis was performed by using 20–20 mL of 70% ethyl alcohol.^{40,51} The intervention is depicted in Figure 1.²⁰

Results

We performed PRNCPB on a total of 16 pancreatic cancer patients. No exclusions occurred before and no dropouts occurred during the period of the study.

Baseline characteristics

Gender and age distribution of the patients were as follows: five men (rounded mean age: 57 years) and eleven women (rounded mean age: 66 years) were enrolled in the study. Comorbidities are depicted in Table 2.

Primary outcomes

- Five days prior to the onset of the study, subjects were at step 3 of the analgesic ladder. Each patient used a constant and high dose of major opioid and adjuvant analgesics. An increase in the dose of analgesics was not possible because of unbearable side effects. According to the WHO, the next analgesic step is the use of invasive pain therapy.

Pain intensity significantly decreased in the post-treatment period compared with pretreatment period based on VAS (Wilcoxon's test $P < 0.001$; effect size: 0.632 and chi-squared test: $P < 0.001$; Figure 2).

- After NCPB, patients still had to continue taking oral analgesics, but their doses decreased compared with pretreatment dose. Although opioids could not be omitted in any of the cases, primarily because of metastatic pain, in each patient the need for previously taken pain medication decreased, either in strength (morphine could be dropped and replaced by dihydrocodeine) or dose, and no patient needed dose increase (Table 3).

Secondary outcomes

Results from the SF-36 survey revealed that pain reduction significantly improved (Wilcoxon's test, after Bonferroni–Holmes correction) at $P < 0.05$ in five out of the eight dimensions (Table 4 and Figure 3). All but three dimensions increased significantly with median effect sizes.

Side effects and complications

The retrocrural PRNCPB has been reported to result in fewer side effects compared with NCPB performed by other

Figure 1 Anatomy of percutaneous retrocrural neurolytic celiac plexus block.

techniques.^{14,20,40} The most common undesirable effect is the pain caused by the intervention.^{43,54,58} During our study, the minimally invasive treatment resulted in only a short-term local irritation at the site of alcohol injection. Approximately 15–20 minutes following neurolysis, all patients had short-term blood pressure drops, which all normalized within 5–10 minutes. This ratio did not exceed 10% of the baseline value and did not affect consciousness. Blood pressure was mainly normalized spontaneously or by the administration of intravenous fluid, in few cases by 5 mg of ephedrine hydrochloride. Diarrhea,^{40,60} postbleeding, neurological symptoms, acute abdominal symptoms, or other severe

adverse effects or complications reported in the literature were not observed.^{8,25,29,31,44}

Discussion

Main findings

1. Patients with severe pain were included in the study, whose doses of systemic combined analgesics were not increased due to the nontolerable side effects, but the intensity of the pain required more powerful analgesia.
2. A minimally invasive intervention was performed under real life outpatient conditions with low material, instrumental, and personal costs.

Figure 2 Pain intensity on VAS scale before and after treatment.

- Validated methods were used to measure the effects of the therapy performed.
- A significant effect could be achieved in pain reduction as well as in the improvement of the QoL.
- Doses of analgesic medication (primarily morphine) could be reduced after the intervention.
- Complications, side effects, and further hospitalization were not detected.

Interpretation and comparison with previously published work

Patients suffering from pancreatic cancer have a very short survival with intense pain influencing the quality of their everyday life. PRNCPB is an effective palliative therapy for the management of chronic, refractory, and celiac plexus-mediated visceral pain.^{43,54,59} It is most often used when analgesic medications fail to control the pain. The number of studies assessing the effect of NCPB on patients' QoL

is limited, and there is inconsistency in the effect of NCPB on QoL.^{14,44–50,60,64,65} This study gives preliminary evidence that NCPB might be effective both in controlling pain and in improving QoL which means that NCPB could provide important benefits for patients suffering from pain associated with advanced pancreatic cancer.

Limitations

Regarding patients

The small number of subjects in our study makes it difficult to draw definitive conclusions. Further, no control group has been included into our study, eg, receiving standard care (waiting control group) or other complementary treatments.

Regarding methods

Due to legal, ethical, and professional reasons, we could not have a blinded control group.

A further limitation is the relatively short follow-up period of 35 days in comparison with a 3- or 6-month follow-up assessment, which has been realized in other studies.^{44,48} Most patients reach step 4 of cancer-related pain treatment (see Table 1) in the last stage of their illness. This was the background to determine a limited period of data collection in the study design. Nevertheless, in the run-on survey, it could be assessed that during the next 35–42 days period after closing the data collection (ie, the first 35 days after the

intervention) no deterioration of symptoms or pain medication was detected.

No concurrent and additional treatments that might have been applied during the follow-up period have been monitored.

To assess the effect of pain relief on patient's QoL, we used the standardized VAS and SF-36 derived from the General Health Survey of the Medical Outcomes Study by Stewart et al.⁶¹ While VAS may be less commonly used than other standard methods in this setting [such as the Care Preferences with Pain, Enjoyment, General Activity Scale (PEG) or the Brief Pain Inventory], out of practical reasons we decided to use VAS. Although SF-36 Health Survey is usually not a first-line standard scale for seriously ill patients, we did not identify any problems or bias.

Bias

Outset bias regarding baseline characteristics of the patients can be described as follows. Age distribution of patients peaks between 55 and 75 years for pancreatic cancer. Although pancreatic cancer is generally more common in men than in women (2:1), the fact that in our study this proportion appeared to be reversed was not likely to result any bias.

Detection, observation, and reporting bias can be estimated as moderate. Differences in distribution and medication of comorbidities should not have affected the outcomes. Selection bias was not detected, as no exclusions occurred before and no dropouts occurred during the period of the investigation.

In our study, we did not evaluate the effect of palliative pain management on survival rate, thus it has been previously demonstrated that effective pain relief does not result in increased survival.^{44,62}

The three dimensions of SF-36, which did not change significantly, were general perception of health and emotional role functioning. As patients are aware of their incurable, end-stage status, it is very likely that it influences their general health perception and emotions.

Generalizability of the treatment – aspects for safety and training

The clinical and practical experience of complications has been rare.^{8,14,20,25,29,31,40,43,44,54,58,63,66} Through official training courses – as established at the University of Pécs – risks are minimized. With sufficient anatomical knowledge, the PRNCPB is easy to acquire. Average neural therapeutic

devices are needed for the intervention in inpatient or outpatient clinical setting.

Conclusion

The results of this study underline the preliminary evidence and our overall clinical experience over 20 years that PRNCPB might help end-stage pancreatic cancer patients in reducing pain and in improving QoL even if only for a short period of time.^{67–70}

Journal of Pain Research

Publish your work in this journal

The Journal of Pain Research is an international, peer reviewed, open access, online journal that welcomes laboratory and clinical findings in the fields of pain research and the prevention and management of pain. Original research, reviews, symposium reports, hypothesis formation and commentaries are all considered for publication.

Submit your manuscript here: <https://www.dovepress.com/journal-of-pain-research-journal>

Dovepress

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
