Purpose: Antibiotic resistance issues associated with microbial pathogenesis are considered to be one of the most serious current threats to health. Fortunately, TiO_2 , a photoactive semiconductor, was proven to have antibacterial activity and is being widely utilized. However, its use is limited to the short range of absorption wavelength.

Methods: In this work, heterostructured $\text{TiO}_2\text{-FeS}_2$ nanocomposites (NCs) were successfully prepared by a facile solution approach to enhance light-induced antibacterial activity over a broader absorption range.

Results: In $\text{TiO}_2\text{-FeS}_2$ NCs, FeS_2 NPs, as light harvesters, can effectively increase light absorption from the visible (Vis) to near-infrared (NIR). Results of light-induced antibacterial activities indicated that $\text{TiO}_2\text{-FeS}_2$ NCs had better antibacterial activity than that of only TiO_2 nanoparticles (NPs) or only FeS_2 NPs. Reactive oxygen species (ROS) measurements also showed that $\text{TiO}_2\text{-FeS}_2$ NCs produced the highest relative ROS levels. Unlike TiO_2 NPs, $\text{TiO}_2\text{-FeS}_2$ NCs, under light irradiation with a 515-nm filter, could absorb light wavelengths longer than 515 nm to generate ROS. In the mechanistic study, we found that TiO_2 NPs in $\text{TiO}_2\text{-FeS}_2$ NCs could absorb ultraviolet (UV) light to generate photoinduced electrons and holes for ROS generation, including $\cdot\text{O}_2^-$ and $\cdot\text{OH}$; FeS_2 NPs efficiently harvested Vis to NIR light to generate photoinduced electrons, which then were transferred to TiO_2 NPs to facilitate ROS generation.

Conclusion: $\text{TiO}_2\text{-FeS}_2$ NCs with superior light-induced antibacterial activity could be a promising antibacterial agent against bacterial infections.

Keywords: antibacterial agent, antibacterial mechanism, reactive oxygen species, light harvester, light-induced antibacterial activity

Introduction

The vigor and resistance of bacterial pestilences are growing day-by-day, and microbial infections are on the rise, creating serious hazards to human health worldwide. Antibiotic-resistant pathogenic infections can soon increase the mortality rate to millions each year.¹⁻⁵ A photoactive semiconductor, titanium dioxide (TiO_2), with economically feasible and biocompatible properties has shown unique antibacterial activity and has been in use for the past few decades.⁶⁻⁸ TiO_2 was shown to be an effective antibacterial agent under ultraviolet (UV) light irradiation, by generating reactive oxygen species (ROS) which can cause irreparable damage to the cell envelope of microbes.⁹⁻¹¹ The effective generation of radicals such as H_2O_2 , $\cdot\text{OH}$, and $\cdot\text{O}_2^-$ by TiO_2 is attributable to its reactivity to light, and it seems to be more efficient when doped or conjugated with other transition elements, noble metals, polymers, carbon, nitrogen, sulfur, or boron to form TiO_2 nanocomposites (NCs). TiO_2 NCs showed superior antibacterial activities to multidrug-resistant bacteria because of their ability to

efficiently absorb light and generation ROS.^{12–20} The efficient light absorption of TiO₂ NCs can be ascribed to contracted bandgaps of TiO₂ due to the conjugation of inorganic and organic materials to TiO₂.^{21–32}

To extend the absorption range, the NCs of iron disulfide (FeS₂) nanoparticles (NPs) conjugated with TiO₂ NPs (FeS₂-TiO₂ NCs) were synthesized. Recently, FeS₂-TiO₂ NCs were explored as a novel photocatalyst to harvest the light in the region from UV to near-infrared (NIR) for application in energy storage and conversion.³³ FeS₂ NPs with a small bandgap (~0.95 eV) have been utilized as efficient light harvesters to enhance the absorption from UV to NIR.³⁴ FeS₂-TiO₂ NCs also exhibited high photoelectric cell (PEC) performance for reducing CO₂ to methanol because the bandgap energy of FeS₂-TiO₂ NCs is narrowed to 1.70 eV for significant enhancement of the photocatalytic performance with visible (Vis) light irradiation.³⁵ Furthermore, TiO₂-FeS₂ NCs with photocatalytic applications in the UV-Vis-NIR region have shown great potential to be TiO₂-based photocatalysts in practical applications for highly active photocatalytic hydrogen evolution.³⁶ However, antibacterial applications with the use of photoactive, biocompatible, and low-cost TiO₂-FeS₂ NCs are still limited. The most pressing need is to combat wide bacterial infections in fields such as medicine, food, and water quality with the light-activated antibacterial agent of TiO₂-FeS₂ NCs.

In this work, light-driven catalysts of TiO₂-FeS₂ NCs were synthesized by a hydrothermal process and annealing method. Characterization studies were carried out to validate the structure and optics of TiO₂-FeS₂ NCs using scanning electron microscopy (SEM), transmission electron microscopy (TEM), powder x-ray diffraction (XRD), Raman spectroscopy, and UV-Vis-NIR spectrophotometry. Furthermore, antibacterial activities of TiO₂-FeS₂ NCs were investigated against *Escherichia coli* (*E. coli*) under illumination of simulated AM1.5 sunlight and in the dark. To study light-harvesting properties of FeS₂ NPs, the antibacterial efficiencies of TiO₂-FeS₂ NCs were also examined against *E. coli* under light irradiation with a 515-nm longpass filter. Moreover, to investigate details of the antibacterial mechanism, ROS generation of TiO₂-FeS₂ NCs against *E. coli* was measured before and after light irradiation.

Materials and Methods

Chemicals

Titanium dioxide (P25) (Acros), iron(III) nitrate nonahydrate (Fe(NO₃)₃) (Acros), sulfur (Acros), thioacetamide (TAA)

(Acros), N,N-dimethylformamide (DMF) (JT/Macron), ampicillin (Bioshop), glycerol (Honeywell), lysogeny broth (LB) broth miller (Bioshop), LB agar miller (Bioshop), agar-A (Biobasic), 2',7'-dichlorofluorescein diacetate (DCFH-DA) (Sigma-Aldrich), and Hoechst 33342 (Biotium) were commercially acquired.

Preparation of TiO₂-FeS₂ NCs Onto Carbon Fiber Paper (CFP)

Fe(NO₃)₃·9H₂O (8 mmol), thioacetamide (100 mmol), and TiO₂ (8 mmol, P25) were dissolved in 10 mL DMF and then transferred to a Teflon container. The Teflon container was fixed in an autoclave reactor and placed in a hot-air oven (JOV-40) at 180°C for 18 h. After cooling to room temperature, the solution was centrifuged (Heraeus multifuge X1R, Thermo Scientific) at 4000 rpm for 10 min and washed with ethanol to remove excess organic residues. Afterward, the primary product of FeS₂-NCs was collected and dried in the oven. A mixture of the primary product of FeS₂-NCs (0.1 g) and sulfur powder (0.3 g) was placed in a furnace (Thermofisher Lindberg Blue M) at 500°C for 1 h to obtain the final product of TiO₂-FeS₂ NCs. For antibacterial tests, TiO₂ NPs (0.4 mg), FeS₂ NPs (0.4 mg), and TiO₂-FeS₂ NCs (0.8 mg) were, respectively, drop-cast onto CFP (CeTech) with dimensions of 1 x 2 cm.

Structural and Optical Characterizations

SEM (JEOL JSM-7800F) and TEM (Hitachi HT-7700) were carried out to characterize the structures of the materials used in the work such as TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs. To prepare TEM samples, TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs were dispersed in ethanol and then drop-cast onto a copper mesh. After being air-dried, the copper mesh with the materials was used for TEM characterization. XRD studies were carried out using A Rigaku Miniflex 600 with Cu K α radiation generated at 30 mA and 30 KeV. Scans for XRD were operated from 20° to 70°. Raman data were measured using an Olympus objective Plan N lens at 16 mW. SEM images, TEM images, XRD data, and surface-enhanced Raman spectroscopic (SERS) measurements were used to validate the structural properties of the TiO₂ NPs, FeS₂ NPs and TiO₂-FeS₂ NCs. A UV-Vis-NIR absorption spectrometer (Jasco V-770) was used to detect and validate the optical properties of TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs.

Antibacterial Activity Test

To culture *E. coli*, LB medium was prepared by mixing 5 g of LB broth (Miller) and 1000 mL of sterilized water. *Escherichia coli* (150 μ L) was cultured in medium containing of 3 mL of LB medium and 300 μ L ampicillin (100 μ g/mL) in a shaker at 160 rpm under 37°C for 3 h. The colony-forming unit (CFU) value of the *E. coli* solution was evaluated by the optical density (OD) at a wavelength of 600 nm (OD600). For *E. coli*, OD600 of 1.0 is calculated to be 8×10^8 CFU/mL. In this study, a solution of *E. coli* with an OD600 of 0.1 was utilized for the antibacterial test. For the light-induced antibacterial test, a solar simulator (Enlitech) was used to simulate AM1.5 sunlight. TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs drop-cast onto CFP were immersed in *E. coli* solutions and then TiO₂ NPs, FeS₂ NPs and TiO₂-FeS₂ NCs were irradiated for 3 min with simulated AM1.5 sunlight. After light irradiation, *E. coli* solutions were cultured in a shaker at 160 rpm and 37°C. During culture, the OD600 values of *E. coli* solutions were measured every 30 min. Bacterial growth curves were used to evaluate the antibacterial activities of TiO₂ NPs and TiO₂-FeS₂ NCs under light irradiation.

Analysis of ROS Generation

ROS generation was measured and validated using a 2',7'-dichlorodihydrofluorescein diacetate (H2DCFDA) assay. For the H2DCFDA assay, H2DCFDA can be oxidized by ROS into 2',7'-dichlorofluorescein (DCF). DCF is highly fluorescent and can be measured by fluorescence spectroscopy with excitation/emission at 488/525 nm. The fluorescence intensity of DCF revealed the total amount of ROS production. Furthermore, the dye of Hoechst 33,342 was applied to measure the total amount of bacteria. The fluorescence intensity of Hoechst 33,342 with excitation/emission at 350/461 nm wavelengths showed the total amount of bacteria. For the analysis of ROS generation, in brief, 10 μ M of DCFH-DA and 1 μ g/mL of Hoechst 33,342 were separately added to *E. coli* culture medium in a 96-well plate. Afterward, *E. coli* solutions were incubated at 37°C and 200 rpm for 20 min. After incubation, *E. coli* solutions were centrifuged at 10^4 g for 2 min, and the supernatants were removed. Precipitates were suspended in sterilized water. The washing procedures were repeated once. The fluorescence intensities of DCF (excitation/emission wavelength at 488/525 nm) and Hoechst 33342 (excitation/emission wavelength at 350/461 nm)

were measured on a microplate reader (Thermo Varioskan Flash). For the different numbers of *E. coli* in different experiments, the total amount of ROS was normalized to the total bacterial number. The relative ROS level was calculated by normalizing the ROS level between the experimental group and the control group.

Results and Discussion

Morphological Characterization

The morphologies of TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs were first characterized by SEM as shown in Figure 1A-C, respectively. In the SEM image of Figure 1A, TiO₂ NPs (P25) exhibited a spherical shape and revealed the formation of aggregates. For FeS₂ NPs and TiO₂-FeS₂ NCs, globular aggregates were observed as shown in Figure 1B and C. To further characterize their structures, TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs were examined by TEM as, respectively, shown in Figure 1D-F. As shown in the TEM image of Figure 1D, TiO₂ NPs clearly revealed a spherical shape with an average size of 25 nm. In Figure 1E, FeS₂ NPs exhibited slight aggregates. The blue arrow indicates FeS₂ NPs in Figure 1E. Most importantly, as shown in the TEM image of Figure 1F, TiO₂-FeS₂ NCs exhibited heterostructures composed by TiO₂ NPs (red arrow) and FeS₂ NPs (blue arrow). High-resolution transmission electron microscopy image of heterostructured TiO₂-FeS₂ NCs was shown in the supporting information of Figure S1. Moreover, the energy-dispersive X-ray spectroscopy (EDS) was applied to measure weight percentages of FeS₂ and TiO₂ in TiO₂-FeS₂ NCs. In the supporting information of Figure S2, EDS spectra showed that weight percentages of FeS₂ and TiO₂ in TiO₂-FeS₂ NCs were, respectively, 49.47% and 50.53%. Overall, SEM images, TEM images, and EDS spectra demonstrated the successful preparation of TiO₂ NPs, FeS₂ NPs and TiO₂-FeS₂ NCs for subsequent antibacterial applications.

Structural Analysis of TiO₂-FeS₂ NCs

XRD was utilized to investigate the crystal structure of TiO₂-FeS₂ NCs. In Figure 2, clear XRD peaks at 25.4°, 37.8°, 48.0°, and 54.5° were accordingly cataloged to the (101), (004), (200) and, (211) planes of the anatase phase of TiO₂ (JCPDS 21-1272), and XRD peaks at 27.5° and, 54.4° were accordingly cataloged to the (110) and (211) planes of the rutile phase of TiO₂ (JCPDS 21-1276). XRD peaks of FeS₂ NPs were matched with approved pyrite FeS₂ (JCPDS

42–1340). The principal peaks of FeS₂ NPs at 28.5°, 33.1°, 37.1°, 40.8°, 47.4°, and 56.3° were accordingly cataloged to the (111), (200), (210), (211), (220), and (311) planes of pyrite FeS₂ as shown in Figure 2. Results of XRD studies also revealed the crystalline nature of TiO₂-FeS₂ NCs. To sum up, TiO₂-FeS₂ NCs were composed of TiO₂ NPs and FeS₂ NPs according to SEM and TEM measurements.

Furthermore, Raman spectra of TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs were studied to evaluate and validate their structural properties and confirm the formation of TiO₂-FeS₂ NCs. As shown in Figure 3, Raman frequencies of TiO₂ NPs were 143 (E_g), 395 (B_{1g}), 513 (B_{1g}), and 633 cm⁻¹ (E_g) for the TiO₂ anatase phase. For FeS₂ NPs, there were two strong peaks located at 338 (E_g) and 377 cm⁻¹ (A_g) corresponding to pyrite FeS₂.³⁷ The two weak Raman signals of 220 and 283 cm⁻¹ were attributed to the presence of FeS due to sulfur insufficiency and sulfur vacancies.^{38,39} For Raman spectra of TiO₂-FeS₂ NCs, the peak at 143 cm⁻¹ was attributed to the Raman signal of TiO₂ NPs (E_g), and the two peaks at 338 and 373 cm⁻¹ were, respectively, attributed to Raman signals of E_g and A_g of FeS₂ NPs. Based on the results of Raman spectra, TiO₂-FeS₂ NCs were composed of TiO₂ NPs and FeS₂ NPs. Based on examination of SEM images, TEM images, XRD spectra, and Raman spectra, TiO₂-FeS₂ NCs were successfully prepared by a simple solution process.

Optical Properties of TiO₂-FeS₂ NCs

UV-Vis-NIR spectra were used to investigate the optical properties of TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs. In UV-Vis-NIR spectra of Figure 4, absorption curves of TiO₂ NPs, FeS₂ NPs and TiO₂-FeS₂ NCs are depicted. Photoactivities of TiO₂ NPs were only found in the UV region of the electromagnetic spectrum. Bandgaps of

Figure 3 Raman spectra of TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs.

TiO₂ (anatase) and TiO₂ (rutile) were, respectively, found to be 3.2 and 3.0 eV according to their absorption wavelengths at 388 and 413 nm. Therefore, the absorption spectra of TiO₂ NPs suddenly decreased after 413 nm.⁴⁰ FeS₂ NPs were seen to have absorption in a wide range from Vis to NIR due to their band gap of 0.95 eV. The absorption of TiO₂-FeS₂ NCs was clearly observed from UV to NIR because of the combination of the absorption curves of TiO₂ NPs and FeS₂ NPs.⁴¹ Results of UV-Vis-NIR spectra indicated that the absorption of TiO₂-FeS₂ NCs was extended from UV to NIR compared to that of TiO₂ NPs.

Light-Induced Antibacterial Activity of TiO₂-FeS₂ NCs

To investigate light-induced antibacterial activities, TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs incubated with *E. coli* solutions were irradiated with simulated AM1.5 sunlight and not irradiated. After light irradiation for 3 min, the OD600 value of the *E. coli* solution was found to be 0.85 after culturing for 150 min as shown in the growth curve (green line) of Figure 5A. Without light irradiation, the growth curve of *E. coli* showed no significant change compared to that of *E. coli* with light irradiation for 3 min. To investigate the light-induced antibacterial activity, TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs were incubated with *E. coli* solutions and then irradiated with light for 3 min. As shown in the growth curves of Figure 5A, after light irradiation for 3 min, OD600 values of *E. coli* solutions incubated with TiO₂ NPs (red line), FeS₂ NPs (blue line), and TiO₂-FeS₂ NCs (black line) were, respectively, 0.52, 0.58, and 0.49 after culturing for 150 min. Bacterial growth results indicated that light-induced antibacterial activities increased in the order of FeS₂ NPs, TiO₂ NPs, and TiO₂-FeS₂ NCs. To further examine the light-harvesting capability of FeS₂ NPs in TiO₂-FeS₂ NCs, a 515-nm longpass filter was applied to exclude light wavelengths shorter than 515 nm. As shown in Figure 5A and B, under light irradiation, growth curves of *E. coli* revealed no changes with and without the 515-nm longpass filter. However, with the 515-nm longpass filter, light-induced antibacterial activities of TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs all decreased, as shown in Figure 5B. After light irradiation for 3 min with the 515-nm longpass filter, OD600 values of *E. coli* solutions incubated with TiO₂ NPs (red line), FeS₂ NPs (blue line), and TiO₂-FeS₂ NCs (black line) were, respectively, 0.85, 0.79, and 0.67 after culturing for 150 min. Obviously, with the 515-nm longpass filter, light absorption by TiO₂ NPs was cut off, resulting in no light-induced antibacterial activity. For FeS₂ NPs, the light-induced antibacterial activity was still exhibited because FeS₂ NPs can absorb light wavelengths longer than 515 nm. Moreover, with the light harvester of FeS₂ NPs, the light-induced antibacterial activity of TiO₂-FeS₂ NCs was retained with the use of the 515-nm longpass filter. When using the filter to restrict light wavelengths shorter than 515 nm, the light-induced antibacterial activity of TiO₂-FeS₂ NCs could be attributed to that the light harvester of FeS₂ NPs in the TiO₂-FeS₂ NCs, which could absorb light wavelengths

Figure 5 Growth curves of *E. coli* (optical density, OD 600 nm) of (A) *E. coli* only and with TiO_2 NPs, FeS_2 NPs, and $\text{TiO}_2\text{-FeS}_2$ NCs under light irradiation for 3 min, (B) *E. coli* only and with TiO_2 NPs, FeS_2 NPs, and $\text{TiO}_2\text{-FeS}_2$ NCs under light irradiation for 3 min with a 515-nm longpass filter, (C) $\text{TiO}_2\text{-FeS}_2$ NCs without light irradiation (black line), $\text{TiO}_2\text{-FeS}_2$ NCs under light irradiation for 30 min with a 515-nm longpass filter (red line), and $\text{TiO}_2\text{-FeS}_2$ NCs under light irradiation for 30 min (blue line). All data presented as means \pm SD, n=3 per group.

Abbreviations: *E. coli*, *Escherichia coli*; TiO_2 , titanium dioxide; NPs, nanoparticles; FeS_2 , iron disulfide; NCs, nanocomposites.

longer than 515 nm to generate photoinduced electrons, and then those photoelectrons were transferred to TiO_2 NPs to generate ROS. Furthermore, after light irradiation for 30 min with the 515-nm longpass filter, the final OD600 value of *E. coli* incubated with $\text{TiO}_2\text{-FeS}_2$ NCs was found to be 0.39 as shown in Figure 5C. Without light irradiation, the final OD600 value of *E. coli* incubated with $\text{TiO}_2\text{-FeS}_2$ NCs was 0.83. Most importantly, after light irradiation for 30 min, there was no growth of *E. coli* in the presence of $\text{TiO}_2\text{-FeS}_2$ NCs as a light-activated antibacterial agent. Overall, results of light-induced antibacterial activity suggested that with $\text{TiO}_2\text{-FeS}_2$ NCs, FeS_2 NPs acted as a superior light harvester to absorb light in the Vis and NIR regions to generate photoelectrons, and then the photoelectrons were delivered from FeS_2 NPs to TiO_2 NPs for improved ROS generation.

Investigation of ROS Generation

TiO_2 -based materials were found to possess remarkable antibacterial activities due to ROS generation under UV light irradiation.⁴²⁻⁴⁴ Therefore, to investigate antibacterial activities, ROS generation activities of TiO_2 NPs, FeS_2 NPs, and $\text{TiO}_2\text{-FeS}_2$ NCs incubated with *E. coli* were measured by an H2DCFDA assay with and without light irradiation. In Figure 6, for the control experiment, the ROS level of *E. coli* without light irradiation was set to 1.0. Compared to *E. coli* with light irradiation for 3 min, the relative ROS level revealed no significant change due to no light-induced antibacterial agent being produced. Moreover, without light irradiation, neither TiO_2 NPs, FeS_2 NPs, nor $\text{TiO}_2\text{-FeS}_2$ NCs showed any obvious increases in ROS. With light irradiation for 3 min, relative ROS levels of TiO_2 NPs, FeS_2 NPs, and $\text{TiO}_2\text{-FeS}_2$ NCs were, respectively, 2.51-,

Figure 6 ROS levels of *E. coli* without light irradiation was set to 1.0. Relative ROS levels of *E. coli* after incubation with TiO_2 NPs, FeS_2 NPs, and $\text{TiO}_2\text{-FeS}_2$ NCs with and without light irradiation and a 515-nm filter, respectively. All data presented as means \pm SD, n=3 per group.

Abbreviations: ROS, reactive oxygen species; *E. coli*, *Escherichia coli*; TiO_2 , titanium dioxide; NPs, nanoparticles; FeS_2 , iron disulfide; NCs, nanocomposites.

1.88-, and 3.34-fold higher compared to that of the control experiment. However, under light irradiation with a 515-nm longpass filter, relative ROS levels of TiO_2 NPs, FeS_2 NPs, and $\text{TiO}_2\text{-FeS}_2$ NCs were, respectively, 1.13-, 1.43-, and 1.63-fold higher compared to that of the control experiment. For TiO_2 NPs with light irradiation, relative ROS levels dramatically decreased from 2.51-fold (without the filter) to 1.13-fold (with the filter) because the light absorption of TiO_2 NPs was reduced by the filter. For FeS_2 NPs under light irradiation, relative ROS levels only dropped from 1.88-fold (without) to 1.13-fold (with the filter). The reason

can be attributed to FeS₂ NPs still being able to absorb light at wavelengths longer than 515 nm to produce photoelectrons for ROS generation. For TiO₂-FeS₂ NCs, relative ROS levels decreased from 3.34- (with light irradiation) to 1.64-fold (with light irradiation and the filter). Under light irradiation with the 515-nm filter, the light-induced antibacterial activity of TiO₂-FeS₂ NCs suggested that photoelectrons generated by FeS₂ NPs in TiO₂-FeS₂ NCs were transferred to the conduction band of TiO₂ NPs to generate more ROS (1.63-fold) compared to that of only FeS₂ NPs (1.43-fold). For TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs, results of the ROS tests were consistent with measurements of antibacterial activities.

To further examine the effect of ROS, the morphologies of *E. coli* incubated with TiO₂-FeS₂ NCs before and after light irradiation were characterized by SEM. As shown in Figure 7A, after incubation with TiO₂-FeS₂ NCs, *E. coli* revealed compact membrane structure without light irradiation. However, with light irradiation for 3 min, *E. coli* incubation with TiO₂-FeS₂ NCs appeared slight membrane rupture as indicated by the yellow arrows in Figure 7B. Furthermore, the complete rupture of *E. coli* membrane was observed as indicated by the white arrows. In high-resolution SEM image of Figure 7C, the slight membrane rupture and complete rupture of *E. coli* membrane were respectively indicated by the yellow arrow and the white arrows. The results indicated that in the system of TiO₂-FeS₂ NCs, under light irradiation, the increases of ROS generation enhanced for the destruction of bacterial membrane.⁴⁵⁻⁴⁷

Mechanism of Light-Induced Antibacterial Activity of TiO₂-FeS₂ NCs

Bandgaps of TiO₂ NPs and FeS₂ NPs were, respectively, found to be 3.2 and 0.95 eV in the UV-Vis-NIR region of the electromagnetic spectrum. The combination of TiO₂ NPs

and FeS₂ NPs was demonstrated to have increased photoactivity. Herein, TiO₂-FeS₂ NCs were also demonstrated to have superior light-induced antibacterial activity compared to that of only TiO₂ NPs or only FeS₂ NPs. A schematic of the mechanism of light-induced antibacterial activity of TiO₂-FeS₂ NCs is shown in Figure 8. With reference to the normal hydrogen electrode (NHE), values of the conduction band (CB) and valence band (VB) of TiO₂ NPs were -0.2 and 3 eV, respectively. Therefore, TiO₂ NPs can absorb UV light to generate photoinduced electrons and holes for ROS production, including ·O₂⁻ (-0.16 eV) and ·OH (2.32 eV). For FeS₂ NPs, CB and VB were, respectively, -0.5 and 0.45 eV. In TiO₂-FeS₂ NCs, FeS₂ NPs acted as light harvesters to absorb light from Vis to NIR to produce photoinduced electrons and holes. Furthermore, the photoinduced electrons in the CB of FeS₂ NPs were transferred to the CB of TiO₂ NPs to facilitate ROS generation. Overall, the light-induced antibacterial activity of TiO₂-FeS₂ NCs was enhanced by the light harvesters of FeS₂ NPs due to the broad range of light absorption from UV to NIR.

Conclusions

TiO₂-FeS₂ NCs were successfully synthesized by a simple solution process, and their structural and optical properties were validated by SEM, TEM, XRD, Raman spectroscopy, and UV-Vis-NIR spectroscopy. TiO₂-FeS₂ NCs exhibited a broad range of light absorption from UV to NIR, because of the combination of the absorptions of TiO₂ NPs and FeS₂ NPs. In TiO₂-FeS₂ NCs, FeS₂ NPs acted as a superior light harvester to increase light absorption from the Vis and NIR ranges. With light irradiation for 3 min, OD600 values of *E. coli* solutions incubated with TiO₂ NPs, FeS₂ NPs, and TiO₂-FeS₂ NCs were, respectively, 0.52, 0.58, and 0.49 after culturing for 150 min, indicating that the best antibacterial activity was with TiO₂-FeS₂ NCs. Light-induced antibacterial

The white arrows indicated the complete rupture of *E. coli* membrane.

Abbreviations: SEM, scanning electron microscopy; *E. coli*, *Escherichia coli*; TiO₂, titanium dioxide; FeS₂, iron disulfide; NCs, nanocomposites.

Figure 8 Schematic illustration of the transfer of photoinduced electrons from FeS₂ NPs to TiO₂ NPs in TiO₂-FeS₂ NCs for ROS generation under ultraviolet, visible, and near infrared light illumination.

Abbreviations: FeS₂, iron disulfide; NPs, nanoparticles; TiO₂, titanium dioxide; NCs, nanocomposites; ROS, reactive oxygen species.

activities of FeS₂ NPs, TiO₂ NPs, and TiO₂-FeS₂ NCs can be attributed to ROS generation. Under light irradiation, relative ROS levels increased in the decreasing order of FeS₂ NPs (1.88-fold), TiO₂ NPs (2.51-fold), and TiO₂-FeS₂ NCs (3.34-fold). In TiO₂-FeS₂ NCs, TiO₂ NPs absorbed UV light to generate photoinduced electrons and holes for ROS generation, including $\cdot\text{O}_2^-$ and $\cdot\text{OH}$. Furthermore, FeS₂ NPs in TiO₂-FeS₂ NCs harvested the light from Vis to NIR to produce photoinduced electrons, and then the photoinduced electrons from FeS₂ NPs were transferred to TiO₂ NPs to facilitate ROS generation. Our work demonstrated that TiO₂-FeS₂ NCs with superior light-induced antibacterial activity could be a potential antibacterial agent for future antibacterial applications in fields such as medicine, food, and water quality.

Acknowledgments

This work was financially supported by MOST109-2636-E-038-001, MOST 109-2113-M-038-005-MY2, Taipei Medical University and the Higher Education Sprout Project by the Ministry of Education (MOE) in Taiwan. We would like to acknowledge Yuan-Chin Hsiung, Chun-Chih Liu and Dr. Chi-Ming Lee for her/his excellent technical support at the TMU Core Facility Center.

International Journal of Nanomedicine**Dovepress****Publish your work in this journal**

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch[®], Current Contents[®]/Clinical Medicine,

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
