Purpose: Adherence to disease-modifying therapies (DMTs) in multiple sclerosis (MS) is a complex and multidimensional phenomenon. Identifying the predictors of therapeutic adherence in MS will guide the design of interventions to improve health outcomes. Our aim was to assess the degree of adherence to pharmacological treatments, assess the relationship between patient-related factors and pharmacological adherence and to identify predictors of adherence to pharmacological treatments in patients with MS in Spain.

Patients and Methods: A cross-sectional nationwide study was carried out in Spain between December 2020 and September 2021. The web-based evaluation protocol consisted of a self-questionnaire survey designed ad hoc and the application of validated questionnaires to assess adherence, as well as beliefs about medication and quality of life. Predictor variables of adherence to MS treatment were assessed using multivariate analysis.

Results: A total of 152 patients with MS participated (mean age: 44 years; 64% were female; and 78% had relapsing-remitting MS). Seventy-three percent of the patients reported being adherent to their pharmacological treatment for MS. Forgetfulness was the most common cause of non-adherence. Necessity beliefs and concerns beliefs were not statistically associated with adherence. The adherent group shows statistically significant better levels of quality of life in the cognitive function subscale than the non-adherent participants ($p=0.040$). Role limitations-emotional, emotional well-being and overall quality of life were not significantly associated with adherence. Predictors with a statistical association with adherence to treatment were years of education ($OR=0.79$; 95% CI: 0.65–0.96; $p=0.020$) and intravenous treatment ($OR=3.17$; 95% CI: 1.07–9.45; $p=0.038$).

Conclusion: We found an adequate adherence to pharmacological treatment. Low education and intravenous treatment were significant predictors of adherence to DMTs.

Keywords: adherence, disease-modifying therapy, medication belief, quality of life

Introduction

Multiple sclerosis (MS) is a chronic disease of the central nervous system that affects 2.8 million people in the world.¹ However, despite the fact that the health condition of people with MS seems to have improved over the last decade,² the disease has a great impact on personal, social and healthcare factors due to its tendency to produce disability in young adults, its negative impact on work, care needs and treatment costs.³

Although there is no cure at the moment, the availability of disease-modifying therapies (DMTs) has increased in recent years. However, to achieve the full therapeutic value of these treatments in MS patients, adherence is essential.⁴

A systematic review in MS indicates that rates of adherence to pharmacological treatments range between 52% and 93%, depending on the measurement methods used in the studies, which are very heterogeneous (self-report, electronic monitoring or pharmacy-based claims).⁵

Specifically, a study carried out in Spain reports figures of 71% for adherence to DMTs in patients with MS.⁶ In MS, a lack of therapeutic adherence can influence the evolution of the disease (greater risk of relapse and higher level of disability), the quality of life of patients and their emotional well-being, as well as the associated healthcare cost (greater number of hospitalizations and emergency hospital visits).^{7,8}

Together with the pharmacological treatments for MS, rehabilitation treatments and healthy habits play a fundamental role in the control of this pathology. Not smoking, engaging in moderate physical activity, eating a balanced diet, maintaining optimal levels of vitamin D, avoiding stress, not consuming toxic substances and following rehabilitation treatments are some of the general recommendations for people with MS.^{9,10} The definition of adherence therefore includes pharmacological treatments but also lifestyle changes.¹¹

Adherence is a complex and multidimensional phenomenon. The World Health Organization (WHO) categorizes the predictors that influence therapeutic adherence into five dimensions: social and economic factors (eg, age or education) health care team and system-related factors (eg, patient–doctor relationship), condition-related factors (eg, level of disability), therapy-related factors (eg, duration of treatment) and patient-related factors (eg, beliefs about medication or psychological aspects).¹² In MS, a variety of factors were associated with adherent patients, including age, cognition, depression, treatment satisfaction, duration of the disease, severity of disease, comorbidities, route of administration, perceived lack of efficacy and adverse effects of the drugs.^{5,13}

The reasons for non-adherence in MS are complex but can be addressed through appropriate interventions by health professionals,¹⁴ especially those factors that can be modified, such as beliefs about medication. Only a few studies have jointly assessed these psychological predictors of non-adherence in the MS population. Therefore, identifying the predictors of therapeutic adherence in MS will act as guidance for the design of interventions in order to improve health outcomes and promote self-management of treatment and disease in patients with MS.

This study aims to 1) assess the degree of adherence to pharmacological treatments in MS patients; 2) assess the relationship between patient-related factors (patients' beliefs and quality of life) and pharmacological adherence; and 3) identify predictors of adherence to pharmacological treatments in patients with MS in Spain.

Materials and Methods

Design

This is a cross-sectional and nationwide study to assess predictors of therapeutic adherence in MS in Spain. Data were collected using a self-questionnaire online. This study is reported following the STROBE guidelines¹⁵ and approved by the Francisco de Vitoria University Research Ethics Committee (31/2020). The research was conducted in accordance with the principles of the Declaration of Helsinki. Informed consent was obtained from all participants, and the data were collected anonymously.

Setting

The study was carried out in Spain between December 2020 and September 2021. The questionnaire underwent pilot testing previously to ensure that patients understood all questions and the usability of the online tool. The pilot survey was completed by 10 participants with MS from a patient association (AEFEM Henares) who met all the inclusion criteria. No modifications had to be made to the questionnaire after the pilot test.

This study included people with MS from 13 autonomous regions. Patients were included from patient associations which are members of the AEDEM-COCEMFE federation (Asociación Española de Esclerosis Múltiple, an entity that is made up of 47 MS patient associations nationwide) and from hospitals by healthcare professionals (neurologists, nurses, psychologists and general practitioners).

Participants

A total of 152 patients with MS met all the inclusion criteria, which comprised patients 18 years or older, diagnosed with MS and receiving DMT for at least 6 months before enrollment. Patients unable to complete the self-administered questionnaire online on their own or with help from a caregiver (severe cognitive impairment, major psychiatric disorders or functional reasons) were excluded.

To determine the sample size, we considered 55,000 MS patients in Spain (data from the Spanish Society of Neurology), and with a 95% confidence level, a sampling error of 8% and a generic proportion of 0.5, we calculated a sample size of 150

participants. A consecutive non-probabilistic sampling method was used. Patients were identified by healthcare professional collaborators consecutively by order of attendance to their habitual follow-up consultations in hospitals or associations.

Variables and Measurements

The study variables are depicted in [Figure 1](#), which groups the predictors into the WHO dimensions.¹² Self-reported adherence to DMT 6 months prior to the study was assessed using the standardized Morisky-Green test.¹⁶

The web-based evaluation protocol consisted of a self-questionnaire survey designed ad hoc and the application of validated questionnaires.

The validated scales included the Morisky-Green questionnaire,¹⁶ the Beliefs about Medicines Questionnaire (BMQ)¹⁷ and four subscales (role limitations-emotional, emotional well-being, cognitive function and overall quality of life) from the Multiple Sclerosis Quality of Life-54 (MSQOL-54).¹⁸

Self-Questionnaire

A self-questionnaire web-based survey with 143 items was developed for this study arranged into seven areas: 1) Socio-demographic factors (13 items); 2) Condition-related factors and therapy-related factors (11 items); 3) Adherence to DMT (21 items); 4) Adherence to rehabilitation treatments (22 items); 5) Adherence to healthy habits (26 items), 6) Information access (12 items); and 7) Psychological and cognitive factors (38 items). Questionnaire items were completed through dichotomous closed questions, Likert-type scales or multiple responses.

Ad hoc items were developed by trained researchers based on the results obtained in two focus groups with patients and were reviewed by a multidisciplinary team which included a neurologist, a nurse, a neuropsychologist, a pharmacist and a patient association representative.

Morisky-Green Questionnaire

Adherence to DMTs was measured using the Morisky-Green questionnaire,¹⁶ validated in the Spanish population.¹⁹ The scale has been widely used in numerous studies and several chronic diseases and has adequate reliability and internal consistency (Cronbach's $\alpha = 0.61$).¹⁶ The Morisky-Green questionnaire scale includes four items with yes/no answers. Patients were considered non-adherent to treatment if they answered “yes” to any of the questions.

Beliefs About Medicines Questionnaire (BMQ)

The Beliefs about Medicines Questionnaire was used to assess beliefs about DMTs.¹⁷ The validated version in Spanish was used.²⁰ The 10-item questionnaire contains two subscales: Specific-Necessity Beliefs and Specific-Concerns Beliefs. Horne et al were the first to present data supporting the reliability and the criterion-related and discriminant validity in

Figure 1 Study model.

different chronic medical conditions.¹⁷ In the MS population, Cronbach's Alpha was $\alpha = 0.84$ for the BMQ Specific-Necessity Beliefs scale and $\alpha = 0.69$ for the BMQ Specific-Concern Beliefs scale.²¹ Each subscale includes 5 items, scored on a 5-point Likert-scale from "1" (strongly disagree) to "5" (strongly agree). Item-scores were summed for both subscales and higher scores indicate greater beliefs.

Multiple Sclerosis Quality of Life-54 (MSQOL-54)

Four subscales from the Multiple Sclerosis Quality of Life-54 (MSQOL-54)¹⁸ were selected: role limitations-emotional, emotional well-being, cognitive function and overall quality of life. The MSQOL-54 is an MS-specific instrument to measure quality of life, adapted to the Spanish population.²² The 4 subscales selected from the MSQOL-54 show good internal consistency with Cronbach's alphas ranging from 0.84 to 0.90.¹⁸ The total score for each dimension ranged from 0 to 100, where a higher value indicates better health-related quality of life.

Bias

To avoid selection bias, healthcare professionals from patient associations and hospitals were instructed to consecutively recruit the first eligible patient by order of attendance to their habitual follow-up consultations, from the start date of the study.

A password-protected website was developed for this study and a unique code was assigned to each healthcare professional collaborator, ensuring that participants met all inclusion criteria.

Statistical Methods

Information was collected via an online database, exported to Microsoft Excel (Microsoft Corporation, Redmond US) and analyzed using R 3.6 (R Foundation for Statistical Computing). First, we presented descriptive statistics (eg, means or frequencies) for socio-demographic and health information. Second, we carried out univariate logistic regressions between the adherence to MS treatment and the rest of variables. Any variables with p -values < 0.20 were considered potential variables to be included in the multivariate model. Variables with variance $< 5\%$ were excluded from the analysis. Additionally, the variables "satisfaction with the neurologist", "presence of comorbidities" and "time since MS diagnosis (chronicity)" were initially considered for the multivariate analysis based on previous evidence.^{8,13,23}

Third, we applied the best subsets regression method with the goodness of fit (R^2) metric to identify the variables that best predict the adherence to MS treatment. One of the advantages of this method, compared to other common strategies such as stepwise regression, is the capacity to identify combinations of variables without eliminating any of them in the process.²⁴ The homoscedasticity of the resulting multivariate model was assessed and we considered multicollinearity variance inflation factor values > 5 .

Results

Patient Characteristics

A total of 215 patients with MS completed the survey. Of these individuals, 152 had been treated with a DMT for at least 6 months and were included in the final analysis. Their demographic and clinical characteristics are depicted in Table 1.

Overall, the mean age of participants was 44 years ($SD \pm 9.6$) and 64% were female. Most patients were married or had a partner (67%), did not live alone (90%) and had higher education (86%).

Participants included in the study had been diagnosed for a mean duration of 13.03 years and predominantly had relapsing-remitting MS (78%). The mean time on their current DMT was 5.9 years and approximately 80% of the patients had previously received another DMT.

Regarding rehabilitation treatments and healthy habits, 38.2% received physiotherapy treatment for MS, 17.8% psychological therapy and only 6.6% neuropsychological treatment. 81% of the patients included in the study do not smoke, more than 45% of the patients do physical activity between 3 and 7 days a week, 75% eat a balanced diet and 62.5% take vitamin D.

Adherence

According to the Morisky-Green questionnaire, 73% of the patients reported being adherent to their pharmacological treatment for MS. Forgetfulness (80.5%) was the most common cause of non-adherence in our study. Regarding the type of DMT: 88.4%

patients receiving intravenous treatment were adherent ($p=0.003$), 69.8% of the patients with self-injectable treatment were adherent ($p=0.485$) and 62.5% of the patients were adherent to their oral treatment ($p=0.014$).

Patient-Related Factors and Pharmacological Adherence

In our sample, necessity beliefs and concerns beliefs were not statistically associated with adherence. Results of the specific BMQ are presented in Table 2.

Table 3 presents the results of the selected subscales from the MSQOL-54, which assess quality of life, comparing adherent and non-adherent patients. The adherent group shows statistically significant better levels of quality of life in the cognitive function subscale than the non-adherent participants ($p=0.040$). Role limitations-emotional, emotional well-being and overall quality of life were not significantly associated with adherence, although a tendency to a higher score in the group of adherents can be observed.

Predictors of Adherence to Pharmacological Treatments

A univariate logistic regression analysis was performed to quantify the association between adherence to DMTs and adherence predictors. Factors of the 5 WHO dimensions were included and a total of seven predictors were significantly associated with adherence to MS treatment: 1) social and economic factors: age ($OR=0.96$) and years of education ($OR=0.82$); 2) therapy-related factors: intravenous treatment ($OR=4.60$), alternative therapies not used ($OR=2.45$), vitamin D adherence ($OR=3.29$) and duration of treatment ($OR=0.11$); and 3) patient-

Table 2 Univariate Analyses Between BMQ Scores and Patient Adherence

Medication Beliefs - BMQ	Non-Adherent Mean (SD) n=41	Adherent Mean (SD) n=111	OR	95% CI	p-value
Necessity	17.56 (3.75)	18.84 (3.43)	1.11	1.00–1.23	0.052

Notes: DMT, disease-modifying therapies; *p-values <0.05; **p-values <0.01. ^aVariables with p-values <0.20 were initially considered for the multivariate model. Additionally, the variables “satisfaction with the neurologist”, “presence of comorbidities” and “chronicity” were also included at the discretion of the researchers. The variables that finally remained in the multivariate model were estimated using the best subset selection method. ^bThe following categories are included: no education: 0 years; primary education: 0–6 years; secondary education: 7–10 years; basic higher education (non-university) completed: 12 years; advanced higher education (non-university) completed: 14 years; university education completed: 17 years; postgraduate education completed: 19 years. ^cAccording to the Spanish regulation: levels under 33% are mild (few problems for daily life); levels between 33% and 64% are moderate (significant decrease in capacities); and levels of ≥65% are severe (inability to fend for oneself).

Abbreviations: DMTs, disease-modifying therapies; MS, multiple sclerosis; WHO, World Health Organization.

Discussion

Adherence to DMTs in MS is a complex and multidimensional phenomenon. In this study, we aimed to identify predictors influencing adherence to MS treatment in Spain.

Even though our study included a limited number of patients, it can be considered representative of the MS population since the patient characteristics of our sample, mean age (M=44, SD=9.6) and proportion of patients with relapsing-remitting MS (78%) were consistent with those from a recent Spanish study that reported data from 490 patients with MS.²

Although there is great variability in adherence rates observed in the literature depending on the measurement methods used in the studies, our data were in line with previous studies. The adherence reported in our sample was 73%, which is very similar to the 71% and 75% reported in studies carried out in Spain using the Morisky–Green test^{6,25} and several studies in other countries using self-reported questionnaires that described mean adherence rates of 74%.⁵

Beliefs about DMTs were one of the patient-related factors studied in this research. Our study was focused on understanding how patients’ beliefs about medication could affect adherence, specifically if the perceived necessity of medication for maintaining health (Specific-Necessity Beliefs) is associated with adherence, and if the concerns about the adverse consequences of medication, like dependence or harmful long-term effects (Specific-Concerns Beliefs) could affect adherence.¹⁷ We have not found any significative association between MS patients’ beliefs and therapeutic adherence. Three studies have analyzed adherence in relation to medication beliefs in MS using the BMQ, with similar findings. Neter et al²⁶ did not find significant differences between adherent and non-adherent patients in the necessity and concern beliefs. A German study by Pust et al²¹ also reported lack of significance in the BMQ Specific-Concern scale, and only non-adherent patients in first-line DMT treatment

showed lower scores in the necessity beliefs. Thach and colleagues²⁷ reported that perceived necessity and perceived concern were not associated with adherence to DMTs in the multivariate analysis. These findings are consistent with our data. Interestingly, BMQ necessity and concern scores were somewhat higher in our sample than in Thach's US population, perhaps indicating a more conscious attitude towards medication (patient perceptions of medication benefits and risks), which may be related to our method of recruiting the patients (about 80% belong to a MS patient association). Horne et al²⁸ conducted a meta-analysis of 94 studies using the BMQ in a wide range of long-term pathological conditions. In most of them, a higher adherence was associated with stronger perceptions of necessity and fewer concerns about treatment. This study is the first to be conducted in Spain which looks at medication beliefs in the MS population, therefore more research is needed to validate these data.

The other patient-related factor explored in this study in relation to adherence was quality of life. In our study we found that cognitive function, role limitations-emotional, emotional well-being and overall quality of life presented a tendency to a higher score in the group of adherents, but only cognitive function was statistically significant. This finding is consistent with another Spanish study that reported higher scores in the adherent group for each of the four dimensions of the MSQOL-54 questionnaire for injectable treatments and oral treatments.²⁹ Our results are also in line with other studies^{6,30} which indicate that cognitive impairment is significantly associated with non-adherence. One of the possible consequences of cognitive impairment for adherence is the increase in forgetfulness. Interestingly, forgetfulness is the most common cause of poor adherence in our study and is also indicated in many studies.^{5,13,23}

To our knowledge, there are no studies in our country which address the five dimensions in the WHO model of medication adherence. In other regions, some studies identified several key factors associated with adherence, such as age, gender, disability, depression, cognition or treatment satisfaction.^{5,13,14,31} In our study, only years of education and the route of administration were significantly associated with adherence to DMTs in the multivariate model.

Regarding the education level, our study shows that the odds of adherence decreased with years of education (OR=0.79; $p=0.020$), so we found higher adherence among patients with a lower education. In line with our results, a multicenter study conducted with $n=2566$ MS patients reported that completion of university education was a predictor of non-adherence.²³ In a Norwegian study on follow-up of new diagnosis MS patients, high education was also a risk factor for stopping DMTs.³² However, these results are not consistent with those reported in other chronic conditions¹²; therefore, more studies with the MS population are needed to explain these data. Considering higher education level as a predictor of poor adherence, these persons are probably more informed regarding their disease and treatment and are more independent to make decisions. Healthcare professionals should be aware of this fact, since it seems contrary to general beliefs in other chronic pathologies, and patients with a higher education level may be at a greater risk of non-adherence.

Regarding the administration route, the positive association between intravenous treatment and adherence has been shown in previous studies. In accordance with our findings, a study in Spain⁶ reported that patients with intravenous treatments are more adherent than those with subcutaneous and oral administrations. Another study in Latin America³³ also concluded that the adherence of patients to infusion therapies was higher compared to oral and injectable drugs. A possible explanation for these findings is that intravenous treatments are administered in a hospital by a healthcare professional, while oral and subcutaneous treatments are self-administered at home by the patient and forgetfulness is a major risk of non-adherence.

Suggestions to Improve Adherence

Adherence is essential to optimize the efficacy of treatments in MS patients.⁷ It is important that clinicians who are in regular contact with patients evaluate and provide support to patients at risk of non-adherence.⁸

As our study indicates, patients with a higher education level may be at a greater risk of non-adherence. Since this can be counterintuitive, healthcare professionals should pay special attention to this predictor to reinforce adherence in this patient profile.

As far as possible, when selecting a DMT, besides considering the safety and tolerability of the treatment, it is necessary to take into account the impact of the drug on patient needs and lifestyle.⁸ It is important to involve the patient in the decision-making process for selecting the route of administration. To this end, healthcare providers should be trained in communication skills and psychological competences to support patients.¹³

In the case of oral and injectable treatments, increasing follow-up of patients who self-administer their treatment could improve adherence rates. Additionally, to avoid forgetfulness, it may be useful to perform a cognitive assessment, send reminders or incorporate the caregivers in the treatment plan.⁸

Intervention in therapeutic adherence requires a multidisciplinary and individualized approach for each patient. It is essential that healthcare professionals have adequate training in therapeutic adherence in order to identify patients with a higher risk of non-adherence and select the most appropriate intervention strategy based on the causes of non-adherence.

Limitations

This study has some limitations, which mainly include the relatively small study size and restrictions inherent to patients' reported data. The Morisky–Green test, despite being the most widely used method to assess adherence in the MS population, has the disadvantage that as a self-report, it tends to overestimate adherence.³⁴ Another limitation is the potential recall bias, as patients answered questions regarding aspects some months ago. In addition, we only used four subscales from the MSQOL-54, so the study lacked other potentially relevant data regarding quality of life. Lastly, it is possible that patients who voluntarily agreed to participate in this survey have a more active role in their disease and treatment management, which may affect the results obtained.

Conclusion

In summary, our study assessed the non-adherence factors of the five dimensions in the WHO model in Spain. Most of the participants in the study reported adequate adherence to their pharmacological treatment. Regarding adherence factors, in the multivariate analysis, none of the patient-related factors (medication beliefs, quality of life) were significantly associated with pharmacological adherence. In this study, only low education and intravenous treatment were significant predictors of adherence to DMTs. More research is needed in order to confirm our findings in the MS population in Spain and evaluate the role of several psychological and quality of life variables in adherence to DMTs.

Acknowledgments

We would like to express our thanks to the AEDEM-COCEMFE federation, their associations members, patients and caregivers for their help completing the questionnaire. We would also like to particularly thank the healthcare professionals of the patient associations and hospitals who participated in the recruitment. We wish to express our thanks to the Unidad de Consultoría y Salud from Francisco de Vitoria University for their help with the recruitment. Lastly, we are very grateful to Suportias for their technical and organizational support.

Patient Preference and Adherence

Dovepress

Publish your work in this journal

Patient Preference and Adherence is an international, peer-reviewed, open access journal that focusing on the growing importance of patient preference and adherence throughout the therapeutic continuum. Patient satisfaction, acceptability, quality of life, compliance, persistence and their role in developing new therapeutic modalities and compounds to optimize clinical outcomes for existing disease states are major areas of interest for the journal. This journal has been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
